# 1 Úvod

Zadavatelem této diplomové práce je firma Wikov Gear s.r.o., která je předním výrobcem převodovek pro těžký průmysl a rychloběžných převodovek. Převodovka je zařízení, které pomocí mechanického převodu transformuje velikost síly, pohyb a polohu dle požadavků. Základním typem je jednostupňová převodovka s vnějším ozubením, která transformuje velikost krouticího momentu a otáček mezi hnacím a hnaným hřídelem. Kinetická vazba mezi ozubenými koly je zajištěna nejčastěji odvalováním jednotlivých ploch boku zubů po evolventní křivce. Výhodou této mechanické vazby je minimální přetvoření mechanické energie v jinou, např. tepelnou, a proto má většina těchto převodů velmi vysokou účinnost. Další výhodou je konstantní převodový poměr, na kterém je závislá změna točivého momentu a otáček mezi vstupním a výstupním členem. Tento převodový poměr je stanoven jako podíl průměrů nebo počtu zubů jednotlivých ozubených kol, kde se nazývá menší ozubené kolo pastorkem a větší kolem. Pokud je převodový poměr  $i > 1$ , jedná se o převod do pomala, tzv. reduktor, naopak pokud je převodový poměr  $i < 1$ , jedná se o převod do rychla, tzv. multiplikátor.

## 1.2 O firmě Wikov Gear s.r.o. <sup>[3]</sup>

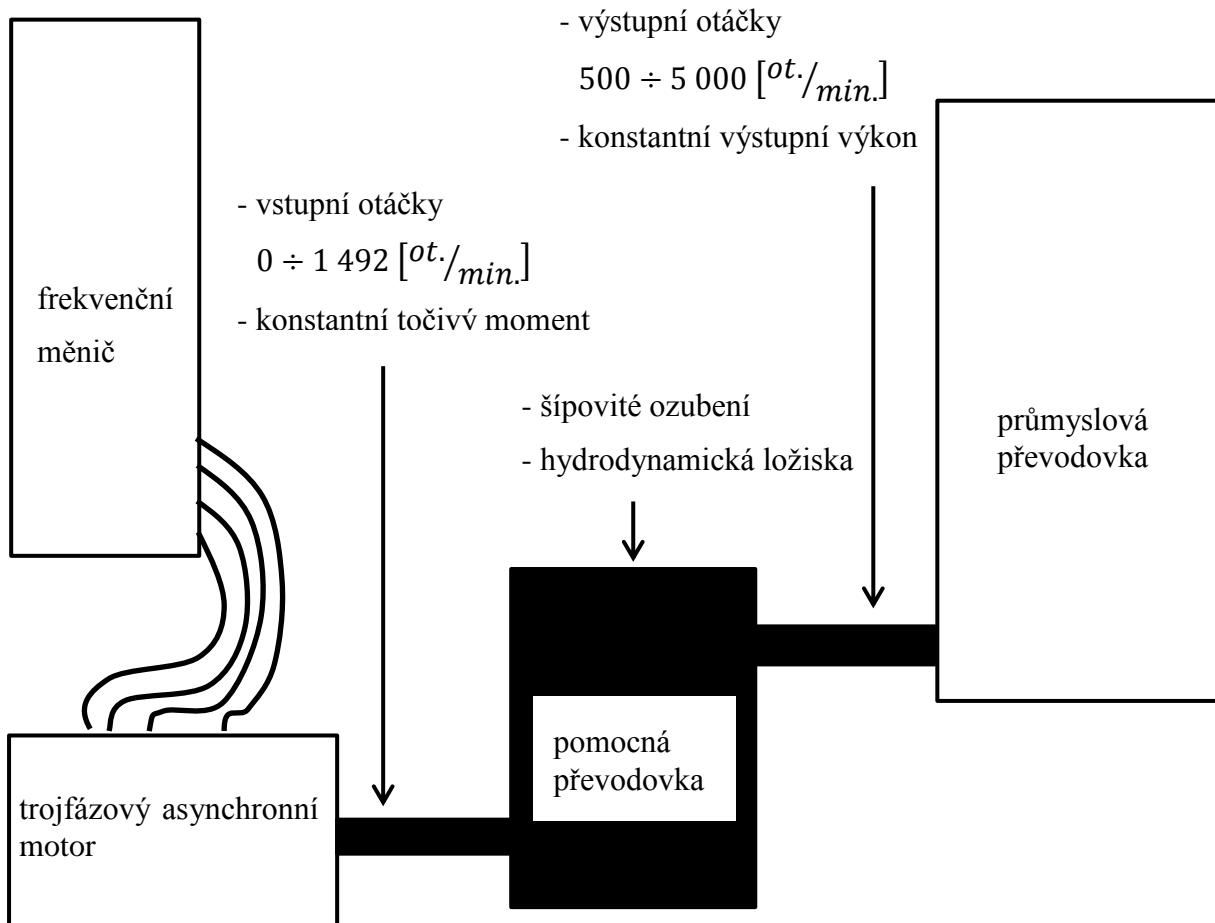

Společnost Wikov je aktivní v mechanickém strojírenství více než 125 let. Přes 80 let je tradičním výrobcem ozubených kol a mechanických převodovek. Název této firmy pochází ze jmen zakladatelů Wichterle-Kovářík, kde byl František Wichterle dědečkem známého českého vynálezce kontaktních čoček profesora Otty Wichterleho. Jedná se tedy o českou firmu. Firma Wikov se dělí na několik společností, mezi které patří právě Wikov Gear s.r.o.

Výrobní závod Wikov Gear s.r.o. se specializuje na:

- design a výrobu převodovek pro:
  - tepelné elektrárny
  - povrchové doly
  - cementárny a zpracování minerálů
  - průmysl těžby ropy a plynu
  - cukrovary
  - chemický průmysl
- design a výrobu rychloběžných převodovek
- výrobu kuželových kol s ozubením Klingelnberg do průměru 1 150 [mm] (lapované a HPG)
- výrobu profilově broušených ozubených kol s přímým vnitřním a vnějším ozubením do průměru 2 500 [mm]
- výrobu frézovaných ozubených dílů do průměru 3 500 [mm]

## 2 Zadání

Cílem této diplomové práce je navrhnout jednostupňovou pomocnou převodovku pro testování průmyslových převodovek, které firma Wikov Gear s.r.o. vyrábí. Hlavním požadavkem na tuto pomocnou převodovku je pokrytí výstupních otáček v rozmezí  $500 \div 5\,000 \text{ [ot./min.]}$  při použití jedné převodové skříně. Toho má být docíleno výměnou jednotlivých soukolí za jiné s potřebným převodovým poměrem, který je potřeba na testování průmyslové převodovky. K testování firma využívá elektrický trojfázový asynchronní motor o výkonu 710 [kW] se jmenovitým počtem otáček  $n = 1\,492 \text{ [ot./min.]}$ . Regulace otáček tohoto motoru je zajištěna frekvenčním měničem. Pomocná převodovka má obsahovat ozubená kola s dvojitě šikmými zuby, jejichž vhodnost je shrnuta v tab. 1. Uložení hnaného a hnacího hřídele má být zajištěno pouze pomocí hydrodynamických ložisek, díky kterým má být zamezeno velkým ztrátám výkonu. Pomocná převodovka má být schopna přenášet nejvyšší možný výkon s rozumným počtem výmenných převodů. Celé schéma zkušebny s potřebným zařízením je zobrazeno na obr. 1.

Výhody:	Nevýhody:
vysoká mechanická účinnost	složitější a dražší výroba
přesné dodržení převodového poměru	nároky na přesnost a tuhost uložení
schopnost přenosu velikých výkonů	hluk a chvění (u většiny těchto převodů)
schopnost dosažení relativně vysokých převodových poměrů	tuhá vazba neumožňuje tlumení rázů a dynamického zatížení
dobra spolehlivost a životnost	malé osové vzdálenosti
relativně malé rozměry	
malá náročnost na údržbu	
krátkodobá přetížitelnost

## 2.1 Specifikace frekvenčního měniče a motoru

Aby bylo možné regulovat otáčky trojfázového asynchronního motoru v určitém rozmezí otáček při konstantním krouticím momentu, je zapotřebí frekvenční měnič. U frekvenčních měničů lze regulovat proud nebo napětí a frekvenci, pomocí které je motor poháněn. Vlivem regulace proudu je na motoru regulován krouticí moment a vlivem regulace napětí a frekvence jsou na motoru regulovány otáčky. Vlivem použití frekvenčního měniče dochází ke ztrátě celkového výkonu motoru o cca 10 [kW]. Protože jsou na motoru regulovány otáčky a tedy i napětí a frekvence, teče přívodní kabeláží do motoru velký proud, proto je kabeláž poměrně robustní. Na motoru tedy lze regulovat otáčky při konstantním krouticím momentu, který nesmí být vyšší než jmenovitý moment motoru, jinak by došlo k jeho přetížení. Vlivem tohoto faktu dochází ke změně vstupního výkonu. Protože požadavkem pomocné převodovky je konstantní výstupní výkon, dojde k poměrně značnému poklesu výkonu oproti výkonu udávaným výrobcem motoru.

### 3 Návrh převodů

Prvním krokem výpočtu bylo stanovení rozdílu vstupních otáček. Tím je umožněno stanovit orientační počet převodů, který pokryje výstupní pole požadovaných otáček. Z těchto parametrů je možné stanovit výstupní výkon z pomocné převodovky, která pokryje požadované spektrum výstupních otáček. Na základě zkušeností konstruktérů z firmy Wikov Gear s.r.o. je účinnost převodovky s šikmým ozubením a použitím hydrodynamických ložisek 98 [%]. Ve výpočtech jsou značeny vstupní členy s indexem 1. Výstupní členy jsou značeny indexem 2.

$$\mu = 98 [\%] = 0,98 [-] \quad \text{účinnost převodovky}$$

$$P = M_k \cdot \omega \quad \text{výkon pro točivé stroje}$$

$$\omega = 2 \cdot \pi \cdot n \quad \text{úhlová rychlosť}$$

↓

$$P = M_k \cdot 2 \cdot \pi \cdot n \quad \text{výstupní výkon}$$

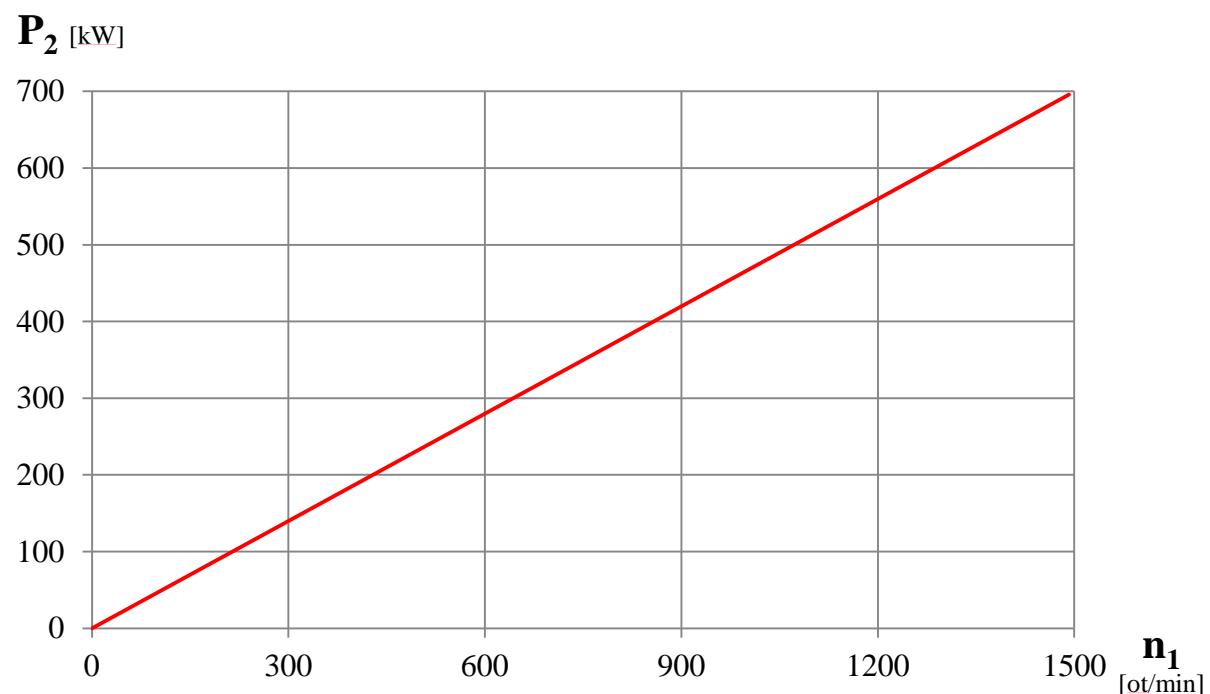

$$P_2 = P_1 \cdot \mu \quad \text{výstupní výkon}$$

↓

$$n_{1\ min.} = \frac{P_2}{M_k \cdot 2 \cdot \pi} \cdot \frac{60}{\mu} = \frac{500\ 000}{4\ 544 \cdot \pi} \cdot \frac{30}{0,98} = 1\ 073 \left[ \frac{\text{ot.}}{\text{min.}} \right]$$

stanovené minimální pracovní otáčky asynchronního motoru

#### vstupní otáčky v závislosti na výstupním výkonu při konstantním momentu

graf 1 závislost výstupního výkonu na otáčkách asynchronního motoru

Z grafu „graf 1“ je patrné, že výstupní výkon bude proměnlivý v závislosti na otáčkách asynchronního motoru. Jelikož v zadání byl stanoven výstupní výkon konstantní při celém spektru zadaných otáček, stanovil jsem tento konstantní výstupní výkon na  $P_2 = 500 [kW]$ . Tento výstupní výkon byl prodiskutován a odsouhlasen se zadavatelem této diplomové práce. Pokud by mohl být výstupní výkon proměnlivý, pohyboval by se v rozmezí  $500 \div 696 [kW]$  ve stanovených pracovních otáčkách asynchronního motoru tj.  $1\,073 \div 1\,492 [ot./min.]$ .

$$n_{1\text{ rozdíl}} = n_{1\text{ max.}} - n_{1\text{ min.}} = 1\,492 - 1\,073 = 419 [ot./min.]$$

..... stanovené rozmezí pracovních otáček asynchronního motoru

### 3.1 Stanovení potřebných převodů

$$i_{12}^* = \frac{n_{1\text{ max.}}}{n_{2\text{ max.}}} = \frac{1\,492}{5\,000} = 0,2984 [-]$$

$$n_{2\text{ min.}} = \frac{n_{1\text{ min.}}}{i_{12}^*} = \frac{1\,073}{0,2984} = 3\,596 \left[ \frac{ot.}{min.} \right]$$

Nejdříve byl spočítán převodový poměr pro maximální vstupní a výstupní otáčky. Z tohoto převodového poměru je možné zpětně dopočítat minimální výstupní otáčky, které nastanou při minimálních vstupních otáčkách.

Postup byl analogicky opakován v programu Excel, dokud nebylo dosaženo na výstupním členu požadovaných  $500 [ot./min.]$ . Na základě tohoto výpočtu bylo stanoveno 7 potřebných převodů, tj. 7 výmenných soukolí. Každý z těchto potřebných převodů je poměrně finančně náročný na výrobu a představuje výrobu dvou hřídelů a dvou ozubených kol, proto jsem se snažil toto číslo dále zredukovat bez dalšího poklesu výstupního výkonu. Jediným řešením, které připadalo v úvahu, bylo otočení celé převodové skříně o  $180 [^\circ]$ , tedy záměnu vstupního hřídele za výstupní a výstupní hřídel za vstupní. Tato skutečnost stanovila potřebný počet převodů na 4 výmenné převody, které mají v tab. 2 stanoveny teoretické převodové poměry. Výhodou je zároveň minimalizace výměny převodů, které pokryjí zadané spektrum výsledných otáček.

$$i_{21} = \frac{1}{i_{12}} \quad \text{převodový poměr v závislosti na změně vstupního členu za výstupní}$$

$i_{21}^*$	$i_{43}^*$	$i_{65}^*$	$i_{87}^*$
3,3512	2,4095	1,7326	1,2460

tab. 2 teoretické převodové poměry pomocné převodovky

Dále následuje návrh počtu zubů pro každý teoretický převodový poměr a stanovení skutečného převodového poměru. Návrh počtu zubů byl optimalizován pomocí programu Excel tak, aby všechny jednotlivé převody měly přibližně shodnou teoretickou osovou vzdálenost a každý z převodů měl na jednom ozubeném kole sudý počet zubů a na druhém kole lichý počet zubů, což by mělo zlepšit celkový chod převodu. Všechna ozubená kola byla navržena pomocí specializovaného programu na ozubení programem KISSOFT. Vstupní data pro návrh jsou shrnuta v kapitole 3.4. Výsledné reporty o parametrech ozubených kol jsou v „Příloha 1“ diplomové práce.

$$i_{12} = \frac{z_2}{z_1} \dots \quad \text{skutečný převodový poměr}$$

#### Výpočet teoretické osové vzdálenosti pro vnější válcové soukolí s šikmými zuby:

$$d_1 = \frac{m \cdot z_1}{\cos \beta} \dots \quad \text{průměr roztečné kružnice prvního ozubeného kola}$$

$$a_{12 \text{ teor.}} = 0,5 \cdot (d_1 + d_2) \dots \quad \text{teoretická osová vzdálenost prvního soukolí}$$

$z$  ..... počet zubů na ozubeném kole

$\beta$  ..... úhel sklonu šroubovice šikmého ozubení

Úhel sklonu  $\beta$  pro šípovité ozubení mi bylo doporučeno konstruktéry z firmy Wikov Gear s.r.o. na minimálně 25 [°]. Pro výpočet všech soukolí jsem stanovil jednotný úhel sklonu  $\beta = 25$  [°]. Základní rozměry jednotlivých soukolí jsou shrnuty v tab. 4.

#### Hrubý návrh modulů jednotlivých soukolí dle Bachova vzorce:

$$m^* = 7,5 (8,6) * \sqrt[3]{\frac{M_k * \cos \beta}{c * \psi * z_1}} [mm]$$

$\psi = 8 \div 12 [-]$  ..... poměrná šířka ozubeného kola

$c = 10 \div 15 [MPa]$  ..... materiálová konstanta

pro šikmé ozubení tj.  $\beta \neq 0$  platí koeficient 7,5

pro přímé ozubení tj.  $\beta = 0$  platí koeficient 8,6

Za krouticí moment  $M_k$  je potřeba dosadit v [ $N \cdot m$ ], protože koeficient 7,5 nebo 8,6 zajišťuje také přepočet na [ $N \cdot mm$ ].

Výsledné orientační moduly pro jednotlivá soukolí jsou shrnuty v tab. 3. Vzhledem k výrobě ozubeného kola jsem stanovil skutečný modul ozubení pro všechny soukolí stejný o velikosti  $m = 6$  [mm].

tab. 6 otáčky a krouticí momenty jednotlivých soukolí při záměně vstupního člena s výstupním

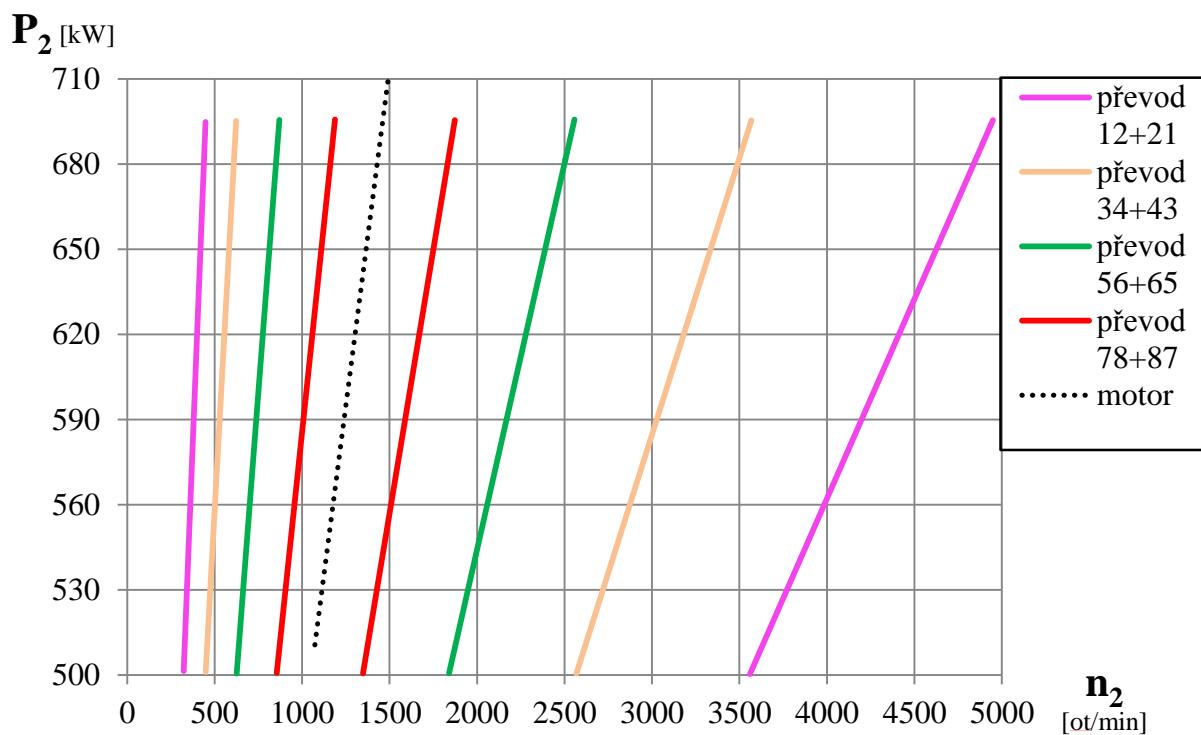

Z tab. 5 a tab. 6 vyplývá, že výsledné převody zkušební převodovky pokryjí výstupní otáčky v rozmezí  $324 \div 623 ; 626 \div 2 557 ; 2 568 \div 4 950$  [ot./min.] s využitím asynchronního motoru, který by ve svém pracovním spektru otáček mohl být připojen bez použití pomocné převodovky. Tyto údaje byly prodiskutovány a odsouhlaseny zadavatelem diplomové práce. Pokud by mohl být výstupní výkon proměnlivý, došlo by pouze ke změně minimálních krouticích momentů na hodnoty maximální, což pro další návrhy nemá vliv.

### 3.3 Výpočet mezery mezi šikmými zuby

Při závěrečné úpravě ozubení brusným kotoučem musí být šípovité ozubení oddělené určitou mezerou  $B$  nebo musí být jednotlivá kola dělená, což někdy neumožňuje konstrukce a také by to mělo za následek složitou a přesnou montáž. Šípovité ozubení se proto vyrábí většinou z jednoho kusu, kde se šírka věnce šikmé části volí přibližně stejná jako výrobní mezera  $B$ . Z obr. 4 lze pomocí matematických vztahů odvodit výslednou mezera  $B$  mezi šikmými zuby, kde je červenou barvou znázorněn brusný kotouč. V tab. 7 jsou vypočítány minimální mezery  $B_{min.}$  pro každé ozubené kolo podle zvolených rozměrů potřebných k výpočtu a dále stanovené (zaokrouhlené) výrobní mezery  $B$ .

### 3.4 Vstupní data pro návrh ozubení programem KISSOFT

V programu KISSOFT jsem provedl návrh jednotlivých soukolí a zkontoval jejich bezpečnost. Výhodou tohoto programu je možnost exportovat výslednou zprávu se všemi potřebnými parametry daného soukolí a zároveň export 3D modelu. Výsledné reporty o parametrech ozubených kol jsou uvedeny v „Příloha 1“ této diplomové práce.

- profil zuba byl zvolen dle normy „ISO 53.2:1997 profil C“ s normalizovaným úhlem záběru $\alpha = 20 [^\circ]$	
- celková šíře soukolí a mezera mezi šípovitým ozubením viz tab. 7, kde celková šíře byla zvolena jako násobek tří potřebné mezery pro výrobu.	

Ostatní koeficienty pro výpočet byly po konzultaci s firmou Wikov Gear s.r.o. ponechány na výchozích hodnotách programu.

Výstupní hodnoty:

Výpočet daného soukolí je téměř okamžitý. Základním výsledkem je návrh profilu zuba (obr. 5), základní rozměrové hodnoty a bezpečnosti pro zadaný zátěžný stav, které jsou uvedeny v tab. 8. Výsledné bezpečnosti jsou uvedeny při maximálním možném zátěžném stavu, tj. maximální krouticí moment, který může na daném soukolí nastat, což nastává u převodů  $i_{21}$ ;  $i_{43}$ ;  $i_{65}$ ;  $i_{87}$ . Ostatní podrobné hodnoty o jednotlivých převodech jsou uvedeny v „Příloha 1“.

## 4 Výběr hydrodynamických ložisek

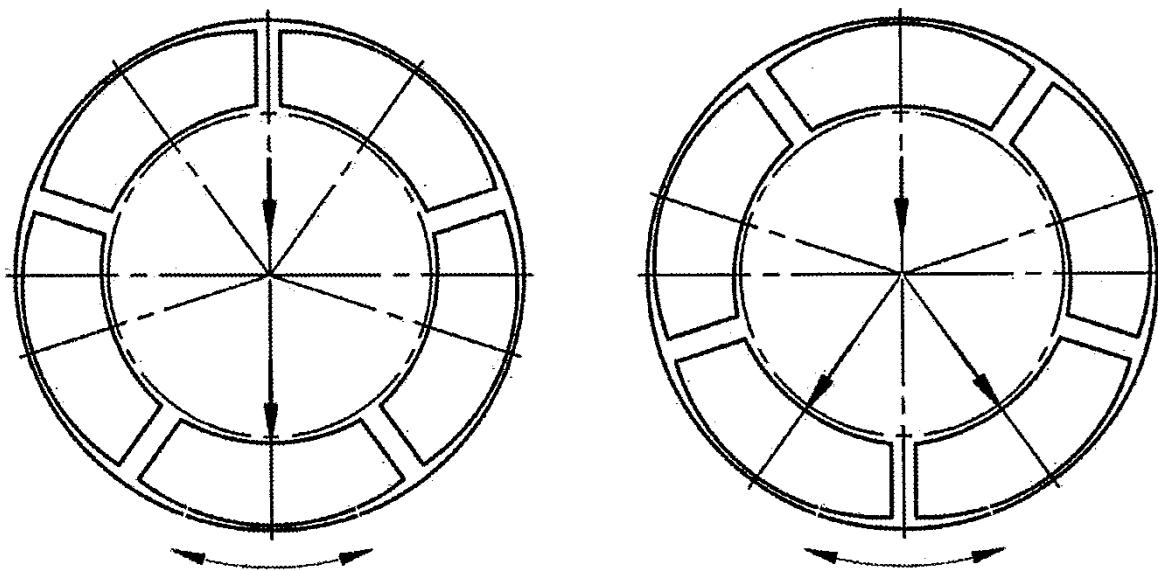

Návrh hydrodynamického ložiska je složitým strojírenským oborem. Věda, která se zabývá problematikou tření, se nazývá tribologie. Při vzájemném pohybu dvou kluzných ploch s použitím kapalinového maziva vzniká tření, které může být mezní, smíšené nebo hydrodynamické viz obr. 6. U hydrodynamických ložiskových párov dochází vlivem zatížení k vytlačování oleje a vlivem rotačního pohybu k vytváření hydrodynamického klínu. Pokud je počet otáček hřídele dostatečně veliký, vzniká v zatížené dolní části prostoru ložiskové vůle účinkem rotace hřídele, viskozity oleje a klínovitého tvaru prostoru ve vrstvě oleje hydrodynamický tlak, který oddělí kluzné plochy hřídele a ložiska a hřídel se vychýlí ve směru rotace, viz obr. 7. Teoreticky by při nekonečně velkém počtu otáček mohl hřídel zaujmout soustřednou polohu v ložisku. Únosnost ložiska závisí na velikosti hydrodynamického tlaku v mazací vrstvě, tj. závisí hlavně na velikosti ložiskové vůle  $\psi$ , kluzné rychlosti a viskozitě maziva  $\eta$ . Vzájemnou závislost těchto veličin určuje Sommerfeldovo číslo  $So = \frac{p \cdot \psi^2}{\eta \cdot \omega}$  a jeho převrácená hodnota se nazývá ložiskové číslo  $a$ . Hydrodynamická ložiska se vyrábí v různých provedeních, která jsou zobrazena v kapitole 4.1. [1]

obr. 6 Stribeckovy křivky [1]

obr. 7 poloha hřídele při hydrodynamickém mazání [1]

Segmentová ložiska jsou výhodná pro vysoké obvodové rychlosti a vyznačují se vysokou tuhostí a útlumem. Tato segmentová ložiska je možné zatěžovat dvěma způsoby, viz obr. 8. Ložisko zatížené mezi segmenty zvýší možné zatížení cca o 1/3 oproti zatěžování na segment. U tohoto typu ložiska se tedy snažíme, aby výsledná reakce působila právě mezi segmenty. Dále jsou všechna hydrodynamická ložiska dělená z technologických a praktických důvodů, viz obr. 9. Vyráběné hodnoty těchto ložisek jsou určeny poměrem šířky k průměru. Nejčastější hodnoty jsou  $B/d = 0,4; 0,5; 0,7; 1 [-]$ . Ložiska mohou být radiální, axiální nebo radiálně-axiální.

## 4.2 Výpočet a výběr vhodných ložisek

Samotný návrh by byl obsahem nové diplomové práce. Firma Wikov Gear s.r.o. nakupuje hydrodynamická ložiska od firmy Waukesha bearings zabývající se touto problematikou. Katalog tohoto výrobce je uveden v „Příloha 2“. K výběru vhodného ložiska je potřeba znát výsledné reakce, které na ně působí. Protože hydrodynamická ložiska jsou poměrně nákladnou záležitostí, budou v této pomocné převodovce použity 4 druhy hydrodynamických ložisek, která budou navržena na maximální zátěžný stav. Tyto 4 ložiska budou tedy využívána pro všechny výmenné převody.

obr. 10 Reakce v uložení vyvozené záběrem zubů a vlastní hmotností soukolí

Z výsledků soukolí v programu KISSOFT dle „Příloha 1“ jsem vyhledal korigovaný čelní úhel záběru  $\alpha_{wt}$  a z působících sil spočetl výslednou reakci  $F_{nw}$ .

$$F_{nw} = \sqrt{F_{tw}^2 + F_{rw}^2}$$

$$\alpha_{wt} = \frac{\operatorname{tg}(\alpha_w)}{\cos(\beta)} = \cos^{-1} \left( \frac{d_{b1;3;5;7} + d_{b2;4;6;8}}{2 \cdot a_w} \right) = \operatorname{tg}^{-1} \left( \frac{F_{rw}}{F_{tw}} \right)$$

příklad výpočtu čelního úhlu záběru pro korigované soukolí

kde  $\alpha_w$  je v programu KISSOFT značen jako  $\alpha_{wn}$ .

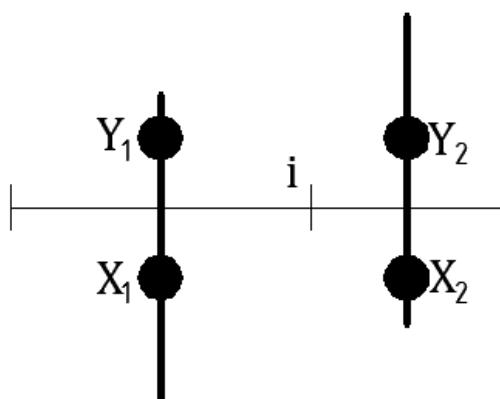

$$F_{X2;1}^i = \sqrt{(F_{nw}^i)^2 + (F_g^X)^2 \pm 2 \cdot F_{nw}^i \cdot F_g^X \cdot \cos(\alpha_{wt}^i)}$$

výpočet výsledné reakce v ložisku s uvažováním vlastní tíhy hřídele

Protože zatím nejsou navržené hřídele (hmotnost a těžiště), zvolím ložiska (velikost) z předběžných sil uvedených v tab. 10, kde jsem výsledné reakce  $F_{nw}$  pro každé ložisko vydělil dvěma, protože ozubená kola budou stejně vzdálena od každého ložiska. Z výsledků jsem dle katalogu „Příloha 2“ zvolil základní průměry hřídelů, kde jsem zvolil poměr šířky k průměru roven jedné. Skutečné maximální reakce působící na ložiska při různých převodových poměrech jsou stanoveny v tab. 11 a příslušné značení na obr. 11. Výsledky vyplývají z návrhu hřídelů, viz kapitola 5. Ložiska označená  $Y_1$ ;  $Y_2$ ;  $X_1$  volím radiální a ložisko  $X_1$  jako radiálně-axiální. Radiálně-axiální ložisko je zvoleno na pomaloběžné hřídeli z důvodů menších výkonových ztrát. Z technologického hlediska montáže nelze použít na obě hřídele ložiska s naklápacími segmenty. Protože je ložisko s naklápacími segmenty výhodnější pro vysoké obvodové rychlosti, budou tyto ložiska umístěna na rychloběžnou hřídel.

**Výběr ložisek:**

Průměr hřídele pod ložiskem  $X_1$  a  $Y_1$  je  $140 [mm]$ . Musí být menší než  $d_{f7} = 335,493 [mm]$ .

Průměr hřídele pod ložiskem  $X_2$  a  $Y_2$  je  $110 [mm]$ . Musí být menší než  $d_{f2} = 133,83 [mm]$ .

**Ložiska  $X_1$  a  $Y_1$**  volím dle tab. 9 v provedení „válec“ s poměrem  $B/d = 0,75 [-]$ . (Obvyklé hodnoty šířky k průměru v provedení válcového profilu  $B/d = 0,5; 0,75; 1$ .)

$$v_{max.} = \omega_{max.} \cdot r = \frac{\pi \cdot d \cdot n_{max.}}{60} = \frac{\pi \cdot 0,14 \cdot 1492}{60} = 10,9 \left[ \frac{m}{s} \right] \dots$$

..... maximální obvodová rychlosť pomaloběžné hřídele (kontrola obvodové rychlosti v tab. 9)

$$B = 0,75 \cdot 140 = 105 [mm] \dots \text{šířka ložiskové pánve}$$

$$S = B \cdot d = 105 \cdot 140 = 14\,700 [mm^2] \dots \text{zátěžná plocha ložiskové pánve}$$

$$p_{max.} = \frac{F_{max.}}{S} = \frac{35\,573}{14\,700} = 2,42 [MPa] \dots \text{měrný tlak (kontrola měrného tlaku v tab. 9)}$$

**Ložiska  $X_2$  a  $Y_2$**  volím dle maximálního zatížení, viz tab. 11, jako segmentová ložiska vyráběná firmou Waukesha Bearings s označením  $TF\ 110 - 110$ . Maximální zatížení tohoto ložiska na segment je  $25,4 [kN]$  a mezi segmenty  $33,9 [kN]$ . Ložisko je čtyř-segmentové. Sudý počet segmentů je výhodný, protože při záměně hnacího hřídele za hnany se reakce na ložisko otočí o  $180 [°]$  a oba zátěžné stavy působí tak mezi segmenty. Výrobce ložiska poskytuje také graf závislosti ztrátového výkonu a průtočného množství oleje na otáčkách hřídele, viz „Příloha 2“.

$$v_{max.} = \omega_{max.} \cdot r = \frac{\pi \cdot d \cdot n_{max.}}{60} = \frac{\pi \cdot 0,11 \cdot 4950}{60} = 28,5 \left[ \frac{m}{s} \right] \dots$$

..... maximální obvodová rychlosť rychloběžné hřídele (kontrola obvodové rychlosti v tab. 9)

$$Q_{max.} = 0,2 \left[ \frac{l}{s} \right] \dots \text{maximální potřebný průtok oleje pro jedno ložisko}$$

$$P_{Z\ max.} = 5 [kW] \dots \text{maximální ztrátový výkon jednoho ložiska}$$

Z důvodů ochrany ložisek před zadřením se u každého ložiska musí kontrolovat teplota oleje v místě působení maximální zátěžné síly. Tyto úhly se vlivem výměnných převodů mění a jsou uvedeny v tab. 11. Jako měřicí úhly bych z výsledků stanovil převody  $i_{78}$  a  $i_{21}$ . Z toho vyplývá, že by bylo potřeba každé ložisko měřit na dvou odlišných místech pootočených o cca  $180 [°]$ , tj. v horní a spodní části převodové skříně.

## 5 Návrh hřidelů

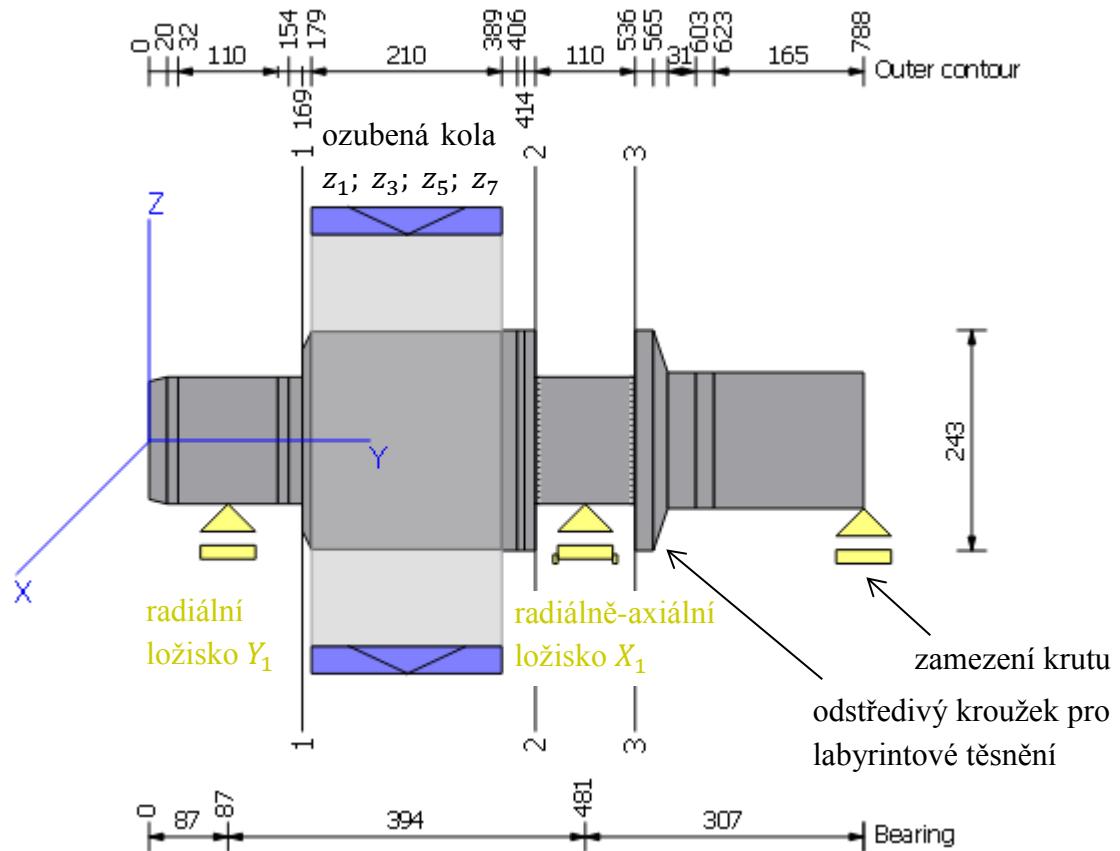

Návrh a výpočet hřidelů byl proveden v programu KISSOFT, viz Příloha 3. Pro zkušební převodovku musí být vyrobeno celkem 8 kusů hřidelí. Z hlediska usnadnění výroby jsem zvolil pro každý převod hřidele stejných rozměrů, viz obr. 12 a obr. 13. Pro výpočet bylo zadáno zatížení převzaté z výsledků jednotlivých ozubení. Důležitým parametrem bylo určení směru rotace otáčení a pozice spolu zabírajícího kola, který určuje výsledný směr a velikost reakcí v ložiskách, viz Příloha 3. Při výpočtu bylo uvažováno s vlastní hmotností hřidele a zadaný materiál jsem zvolil „C45 (1)“. O tom, která ozubená kola budou na hřidel nalisována nebo která budou vyrobena spolu s hřidelí, je uvedeno v kapitole 6. V kritických (vrubových) místech byla provedena kontrola na cyklické namáhání, kde všechny hřidele mají neomezenou životnost. Základní hodnoty výsledků jsou shrnutы v tab. 12 a tab. 13. Maximální průhyby jsou v koncových místech hřidelů, tj. v připojení pro spojku.

## 5.1 Výpočet spoje pro spojku

Připojení hřídele ke kotoučové spojce volím pomocí drážkového spoje, viz obr. 14, kde dovolený tlak je  $p_d = 60 [MPa]$ . Délku rovnobokého drážkování volím  $L = 100 [mm]$ . Výpočet je pouze kontrolou pro navržený typ rovnobokého drážkování s ohledem na rozměry hřidelí.

obr. 14 rovnoboké drážkování

### Rovnoboké drážkování na rychloběžných hřidelích:

$$M_{k \max.} = 4 \cdot 544 [N \cdot m] \quad \text{maximální krouticí moment přenášený rovnobokým drážkováním}$$

**10 x 102 x 108** ..... značení rovnobokého drážkování

$$F_o = \frac{4 \cdot M_{k \max.}}{d+D} = \frac{4 \cdot 4 \cdot 544}{0,102+0,108} = 86 \cdot 552 [N] \quad \text{obvodová síla}$$

$$S_{\text{zatěžovaný}} = 0,75 \cdot \frac{D-d}{2} \cdot L \cdot z = 0,75 \cdot \frac{108-102}{2} \cdot 100 \cdot 10 = 2 \cdot 250 [mm^2] \quad \text{plocha zatěžovaných boků zubů}$$

$$p_{\text{měrný}} = \frac{F_o}{S_{\text{zatěžovaný}}} = \frac{86 \cdot 552}{2 \cdot 250} = 38,5 [MPa] \leq p_d \quad \checkmark \text{ vyhovuje}$$

### Rovnoboké drážkování na pomaloběžných hřidelích:

$$M_{k \max.} = 15 \cdot 078 [N \cdot m]$$

**10 x 130 x 140**

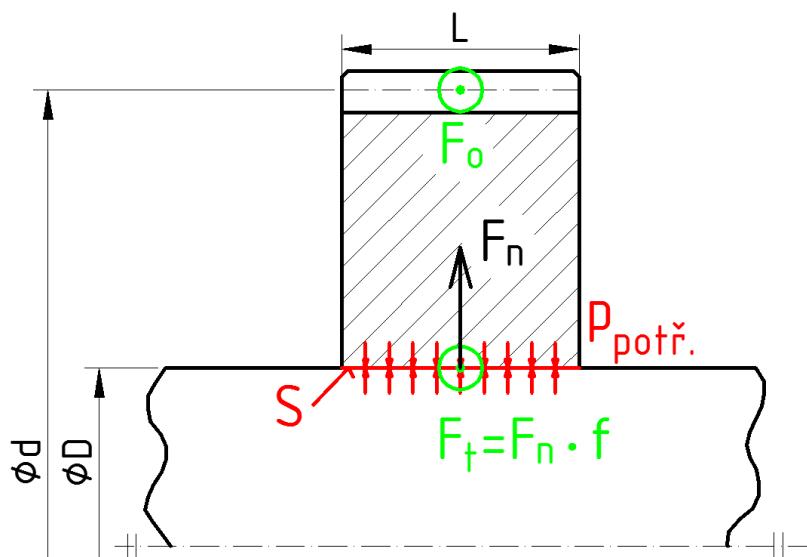

$$F_o = \frac{4 \cdot M_{k \max.}}{d+D} = \frac{4 \cdot 15 \cdot 078}{0,13+0,14} = 223 \cdot 378 [N]$$

$$S_{\text{zatěžovaný}} = 0,75 \cdot \frac{D-d}{2} \cdot L \cdot z = 0,75 \cdot \frac{140-130}{2} \cdot 100 \cdot 10 = 3 \cdot 750 [mm^2]$$

$$p_{\text{měrný}} = \frac{F_o}{S_{\text{zatěžovaný}}} = \frac{223 \cdot 378}{3 \cdot 750} = 59,6 [MPa] \leq p_d \quad \checkmark \text{ vyhovuje}$$

## 6 Nalisování

Ozubené kolo může být na hřídel nalisováno za tepla nebo za studena. Vlivem uložení s přesahem vzniká ve spoji tlak, který umožní přenášet točivý moment z ozubeného kola na hřídel. U rychloběžných převodovek může také dojít k uvolnění spoje vlivem odstředivé síly, která působí na obě hmoty. Proto uvažuji i s touto silou. Z hlediska výroby je lépe obrobitelná hřídel než díra. Proto má díra většinou větší toleranční pole oproti hřídeli. Toleranční pole díry je zvoleno na H7 a příslušná tolerance hřidele musí být dopočítána.

$$S = \pi \cdot D \cdot L \quad \text{plocha přenášející točivý moment}$$

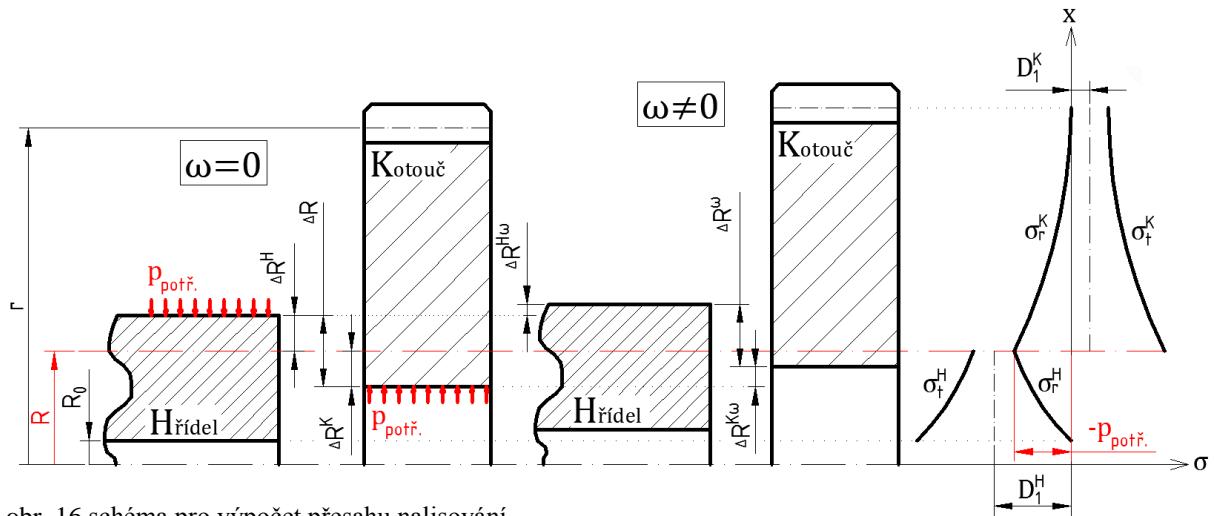

$$S_f = 2,5 [-] \quad \text{bezpečnost lisovaného spoje}$$

$$f = 0,2 [-] \quad \text{koeficient tření mezi hřídelí a ozubeným kolem po nalisování za tepla}$$

$$M_k = F_o \cdot \frac{d}{2} = F_t \cdot \frac{D}{2} \quad \text{krouticí moment pro vyjádření tečné síly pro lisovaný spoj}$$

$$p_{potr.} = \frac{F_t}{S} \cdot S_f = \frac{\frac{F_t}{f}}{\pi \cdot D \cdot L} \cdot S_f = \frac{2 \cdot M_k \cdot S_f}{\pi \cdot D^2 \cdot L \cdot f} \quad \text{potřebný tlak pro přenesení maximální krouticího momentu}$$

$$\Delta R = |\Delta R^H| + \Delta R^K$$

$$\Delta R^\omega = \Delta R + \Delta R^{H\omega} - \Delta R^{K\omega}$$

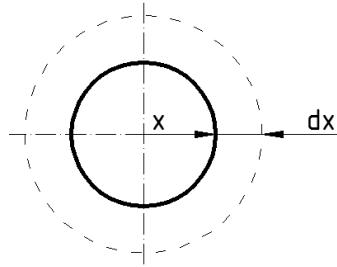

Přetvoření silnostěnné nádoby získáme pomocí poměrné deformace a Hookova zákona, kde  $\nu [-]$  je Poissonovo číslo.

$$\varepsilon_t = \frac{2 \cdot \pi \cdot (x + \Delta x) - 2 \cdot \pi \cdot x}{2 \cdot \pi \cdot x} = \frac{\Delta x}{x}$$

$$\varepsilon_t = \frac{1}{E} \cdot (\sigma_t - \nu \cdot \sigma_r)$$

$$D_2^{K\omega} = D_\omega^K \cdot (3 + \nu^K) \cdot R^2 \cdot r^2$$

$$D_1^{H\omega} = D_\omega^H \cdot (3 + \nu^H) \cdot R^2$$

$$D_2^{H\omega} = 0$$

### 6.2.1 Změna rozměru kotouče

$$\Delta R^{K\omega} = \frac{R}{E^K} \cdot (\sigma_{t(R)}^{K\omega} - \nu^K \cdot \sigma_{r(R)}^{K\omega})$$

$$\sigma_{t(R)}^{K\omega} = 2 \cdot D_\omega^K \cdot [R^2 \cdot (1 - \nu^K) + r^2 \cdot (3 + \nu^K)]$$

po dosazení  $\sigma_{t(R)}^{K\omega}$  a  $\sigma_{r(R)}^{K\omega}$ :

$$\Delta R^{K\omega} = \frac{2 \cdot D_\omega^K \cdot [R^2 \cdot (1 - \nu^K) + r^2 \cdot (3 + \nu^K)] \cdot R}{E^K}$$

### 6.2.2 Změna rozměru plného hřídele

$$\Delta R^{H\omega} = \frac{R}{E^H} \cdot (\sigma_{t(R)}^{H\omega} - \nu^H \cdot \sigma_{r(R)}^{H\omega})$$

$$\sigma_{t(R)}^{H\omega} = 2 \cdot D_\omega^H \cdot R^2 \cdot (1 - \nu^H)$$

po dosazení  $\sigma_{t(R)}^{H\omega}$  a  $\sigma_{r(R)}^{H\omega}$ :

$$\Delta R^{H\omega} = \frac{2 \cdot D_\omega^H \cdot R^3 \cdot (1 - \nu^H)}{E^H}$$

↓

$$\Delta R^{H\omega} < \Delta R^{K\omega}$$

↓

$$\Delta R_\omega = \Delta R^{K\omega} - \Delta R^{H\omega} \quad \text{..... odlehnutí kotouče od hřídele vlivem rotace}$$

Vlivem rotace vzniká odlehnutí kotouče od hřídele o  $\Delta R_\omega$ , proto je potřeba toto odlehnutí přičíst k potřebnému přesahu  $\Delta R$  a na tento celkový přesah  $\Delta R_{celk}$  navrhnut vzhodné uložení.

### 6.2.3 Přesah pro lisování rotujících kotoučů

Následující graf 4 znázorňuje vliv rotace na lisovaný spoj, který by byl uvažován a počítán bez ní. Pro sestrojení grafu jsem použil tyto parametry a konstanty:

$P = 510 [kW]$	přenášený výkon spoje
$\nu = \nu^H = \nu^K = 0,3 [-]$	Poissonovo číslo
$E = E^H = E^K = 2,1 \cdot 10^5 [MPa]$	Youngův modul pružnosti v tahu
$\rho = \rho^H = \rho^K = 7\,860 \left[ \frac{kg}{m^3} \right]$	hustota materiálu
$S_f = 2,5 [-]$	bezpečnost spoje na přenesení točivého momentu
$f = 0,2 [-]$	koeficient tření po nalisování za tepla
$L = 200 [mm]$	délka lisovaného spoje
$d = 500 [mm]$	průměr kotouče
$D = 250 [mm]$	průměr hřídele
$R_0 = 0 [mm]$	rozměry hřídele a kotouče

$$\Delta D = 2 \cdot \Delta R$$

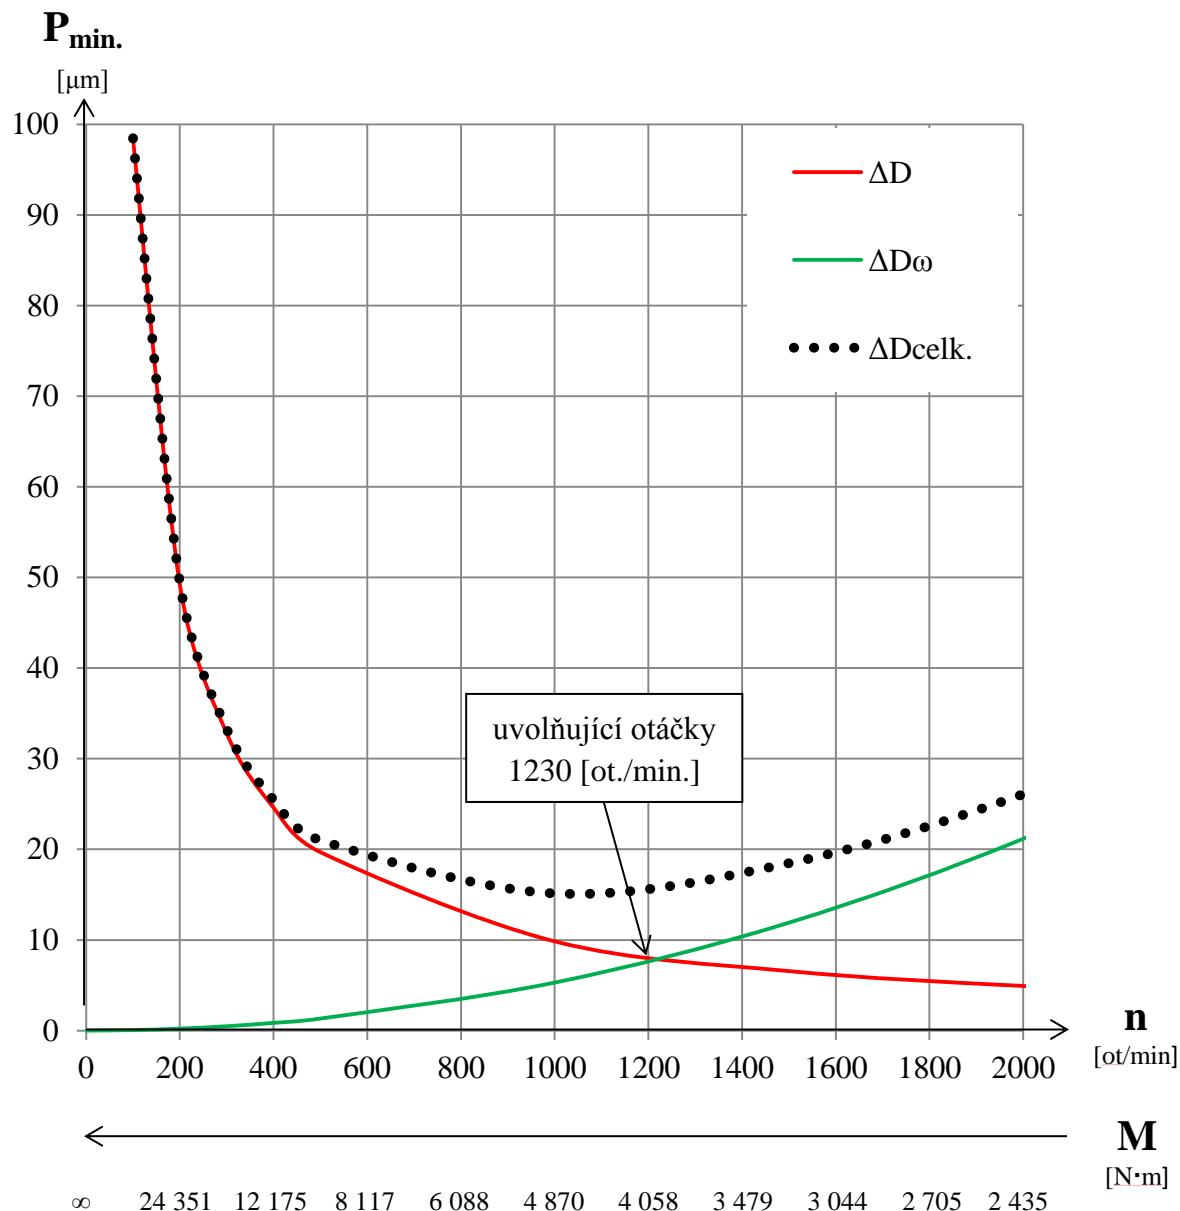

$$\Delta D_\omega = 2 \cdot \Delta R_\omega$$

$$\Delta D_{celk.} = \Delta D + \Delta D_\omega = 2 \cdot (\Delta R + \Delta R_\omega)$$

Uvolňující otáčky lisovaného spoje pro stejný materiál a plnou hřídel:

$$n = \frac{1}{\pi} \cdot \sqrt{\frac{2 \cdot p_{potř.}}{(3 + \nu) \cdot \rho \cdot (r^2 - R^2)}}$$

### Přesah pro nalisování rotujících kotoučů při P=510 [kW]

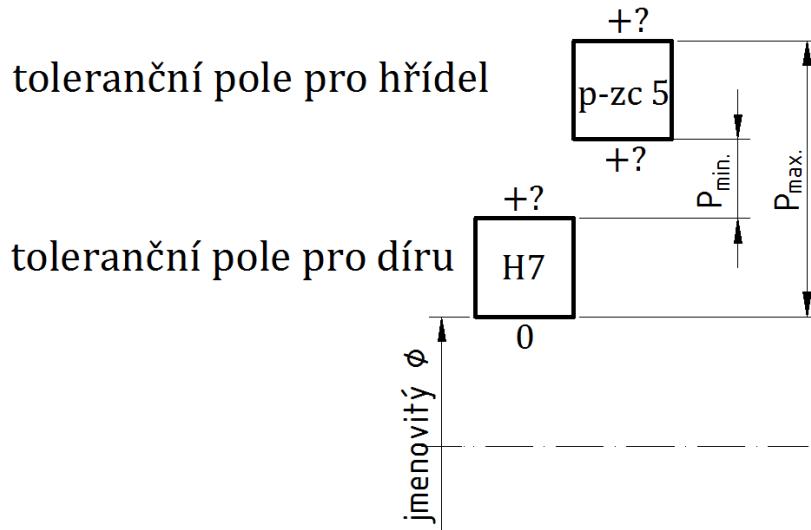

graf 4 minimální přesah pro nalisování rotujících kotoučů při konstantním výkonu

Z grafu je patrné, že pokud spoj dimenzujeme pouze na točivý moment (červená čára) a neuvažujeme otáčení hřídele (zelená čára), stává se spoj od určitého místa poddimenzován od hodnoty cca.  $1/3$  uvolňujících otáček spoje při bezpečnosti  $S_f \approx 1,1$ .

Od tohoto místa směrem k vyšším otáčkám je nutné uvažovat vliv rotace nebo logaritmicky navyšovat bezpečnost spoje na přenesení potřebného točivého momentu. U rychloběžných převodovek je tedy potřeba uvažovat s tímto vloženým odlehnutím. Protože se navržená převodovka pro testování průmyslových převodovek využívá v pomaloběžném i rychloběžném režimu, musí být lisovaný spoj navržen na takový zátěžný stav, který způsobí největší odlehnutí  $\Delta D_{celk.}$

### 6.3 Výběr vhodného uložení

Na základě celkového potřebného přesahu  $\Delta D_{celk.}$  a tolerovanou díru H7 musíme najít minimální přesah uložení  $P_{min.}$ , který může nastat a který musí být větší než  $\Delta D_{celk.}$ .

obr. 20 uložení s přesahem

Jednotlivé uložení každého soukolí je shrnuto v tab. 14.

### 6.4 Ohřátí potřebné pro montáž lisovaného spoje

Rozdíl teplot pro montáž je určen z poměrné deformace a teplotní roztažnosti látky, kde  $\alpha [1/K]$  je součinitel teplotní roztažnosti.

$$\varepsilon_t = \frac{\Delta P_{max.} + \nu}{D} = \alpha \cdot \Delta t$$

↓

$$\Delta t = \frac{\Delta P_{max.} + \nu}{D \cdot \alpha}$$

$$\nu = (0,006 \div 0,012) \cdot \sqrt{D} \quad \text{přibližné vůle pro montáž}$$

$$\alpha = 11 \cdot 10^{-6} \left[ \frac{1}{K} \right] \quad \text{součinitel délkové roztažnosti pro chromovou ocel}$$

## 6.5 Výsledné uložení jednotlivých ozubených kol

Výpočet uložení jednotlivých kol byl proveden pomocí programu Excel, kde byl vybrán nejtěžší zátěžný stav, který způsobí největší potřebný přesah nalisování. Výsledná uložení jednotlivých kol na hřídele jsou zobrazena v tab. 14. Ozubené pastorky  $z_2$  a  $z_4$  nelze kvůli malým rozměrům lisovat a je nutné je vyrobit spolu s hřídelí.

$E = E^H = E^K = 2,1 \cdot 10^5 [MPa]$	Youngův modul pružnosti v tahu
$\rho = \rho^H = \rho^K = 7\,850 \left[ \frac{kg}{m^3} \right]$	hustota materiálu
$S = 2 [-]$	bezpečnost spoje na zatížení vůči $\Delta D_{celk.}$
$f = 0,2 [-]$	koeficient tření po nalisování za tepla

## 7 Návrh převodové skříně

Při návrhu převodové skříně jsem vycházel z požadovaných vlastností zadání a výpočtů. Prvním krokem bylo vygenerování 3D modelů jednotlivých ozubených kol a pastorků. Následně byla vymodelována jednotlivá hydrodynamická ložiska o rozměrech uvedených v „Příloha 2“. Jednotlivé hřídele byly vymodelovány podle výpočtů v kapitole 5.

Uložení jednotlivých převodů s hydrodynamickými ložisky je zajištěno pomocí převodové skříně, která je vzhledem zadání modelována jako svařenec. Převodová skříň musí zajistit všechny potřebné vlastnosti pro funkci převodovky, například mazání všech funkčních komponent, odvod maziva, tuhost, dynamické namáhání, manipulaci, ochranu před nečistotami atd. Pro tuto pomocnou převodovku jsem zvolil dělenou skříň, která se skládá z víka a spodní části. Dělicí rovina se nachází v úrovni os hřídelí. Základem svařované převodové skříně jsou výpalky plechů o různých tloušťkách a bramy (odlévané desky velké tloušťky), ze kterých je převodová skříň tvořena. Materiál převodové skříně musí být zaručeně svařitelný, proto bych k výrobě použil běžnou konstrukční ocel 11 373, která má mez kluzu  $R_e = 220 \text{ [MPa]}$ . Víko a spodní část převodové skříně jsou zobrazeny na obr. 21 a obr. 22. Pro výrobu obou částí jsem využil plechů tloušťky 3; 10; 15 a 30 [mm]. Hmotnost spodního dílu je cca 361 [Kg] a víko cca 323 [Kg]. Spodní část převodové skříně se skládá z celkem 22 plechů a víko je složeno ze 14 plechů. Převodová skříň je 935 [mm] dlouhá, 670 [mm] široká a 585 [mm] vysoká. Dělicí rovina je umístěna ve výšce 310 [mm]. Na obrázcích jsou vyznačeny potřebné svary žlutou barvou.

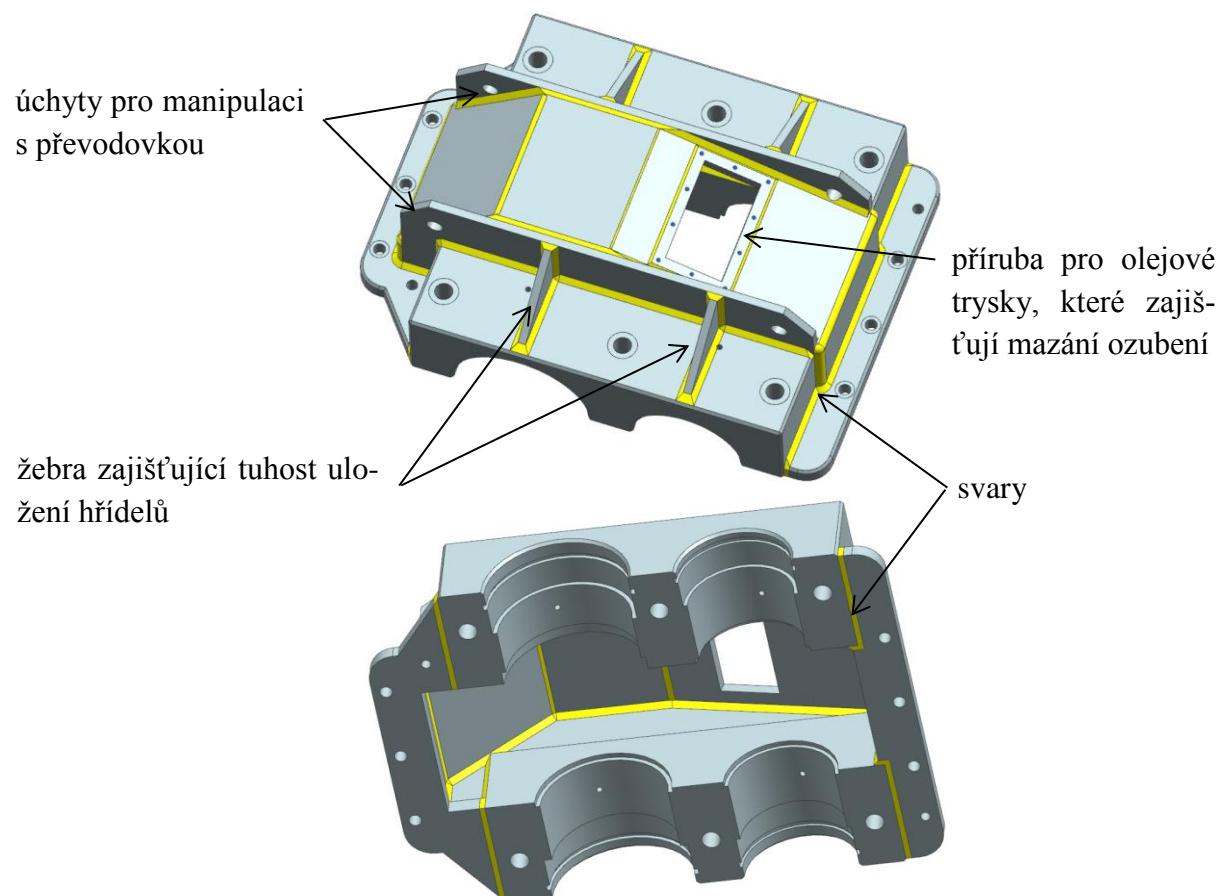

Spojení obou částí převodové skříně je zajištěno dvěma druhy šroubů. Prvním typem je 6 hlavních šroubů vyráběných na míru, které přenášejí zatížení vzniklé od záběru zubů a zamezují tak otevření víka převodové skříně a případné havárii. Druhým typem jsou normalizované šrouby, které zajišťují těsnost převodové skříně po celém obvodu dělicí roviny. Všechny šrouby jsou zajištěny proti povolení druhou maticí. Přesnou polohu spodní části s víkem převodové skříně vymezují dva kuželové kolíky.

Převodová skříň musí být ustavena v požadované poloze na stabilním podloží. Proto jsou ve spodní části přivařeny dvě takzvané patky, za které lze převodovou skříň ustavit např. šrouby nebo upínkami. Pro zvýšení tuhosti a odolnosti proti dynamickému namáhání se převodové skříně opatřují žebrováním, které se zpravidla nachází v blízkosti uložení jednotlivých hřídelí. Další důležitou vlastností převodové skříně je přívod a odvod mazacího oleje do všech potřebných míst. Prvním je způsob mazání ozubeného převodu. Pro kvalitní mazání a minimalizaci ztrát vznikajících např. broděním zubů v olejové lázni je tato pomocná převodovka mazána přímým vstříkem oleje do zubového záběru. Víko převodové skříně je proto opatřeno přírubou, do které se uchytí olejové trysky. Pro šípovité ozubení je doporučen směr otáčení ve směru jednotlivých šípů, aby byl olej vlivem odstředivé síly vytlačován a nedocházelo k jeho případnému přehřívání. Druhým potřebným místem pro mazání jsou hydrodynamická ložiska. Rozvod oleje v ložisku je zajištěn drážkou po obvodu, která je dána výrobcem ložiska. Přístup oleje do této drážek je umožněn vývrtem a drážkou v dělicí rovině ve spodní části převodové skříně, viz obr. 22. Protože vznikem rotace hřídele dochází v hydrodynamickém ložisku ke vzniku tlaku, je potřeba na vnější straně ložiska zajistit dostatečně velký odvod oleje, aby nedocházelo k průsakám oleje přes labyrintové těsnění mimo převodovou skříň.

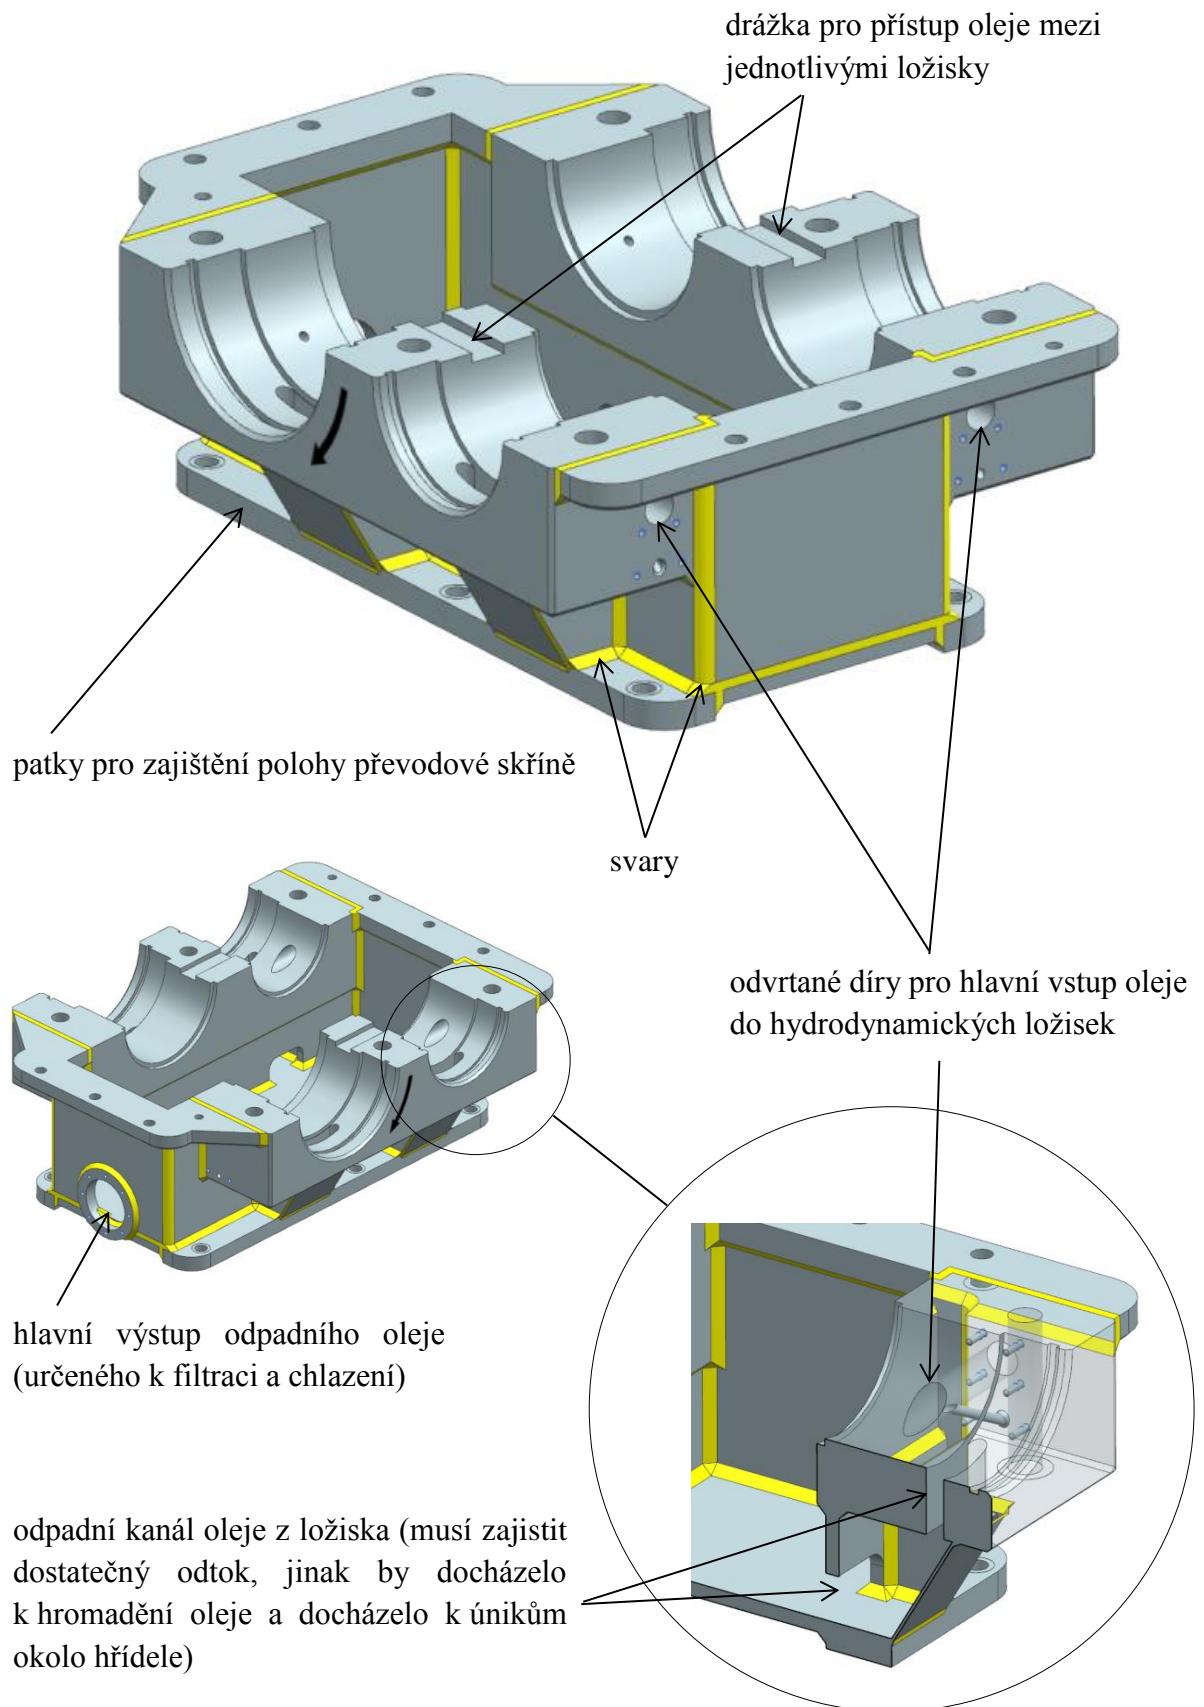

Tento odvod oleje z vnější části ložiska je často řešen prostorem vymezeným dvěma žebry, která jsou překryta tenkým plechem. Do obou míst (zubového záběru a hydrodynamických ložisek) je tedy nezbytně nutný neustálý přísun oleje, proto je nutné odpadní olej z převodové skříně odvádět, filtrovat a chladit, aby se mohl znova využít pro mazání obou funkčních prvků. Hlavní odvod odpadního oleje z převodové skříně musí být dostatečně velký a umístěný na správné straně spodní části převodové skříně. Vlivem vířivých proudů, vznikajících při vlastní rotaci ozubených kol je totiž olej nepřímo vháněn do hlavního odvodu odpadního oleje.

Abychom zajistili bezproblémový chod převodovky, monitorují se určité hodnoty měřením, např. otáčky hřídelů, vibrace, tlak olejové kapaliny nebo teplota oleje v reakci působící v ložiskové pávni. Tyto reakce jsou shrnuty v tab. 11. Pro tuto pomocnou převodovku by byla potřeba měřit teplotu na osmi místech. Tímto měřením se předchází případnému zadření ložisek, která jsou finančně nákladná.

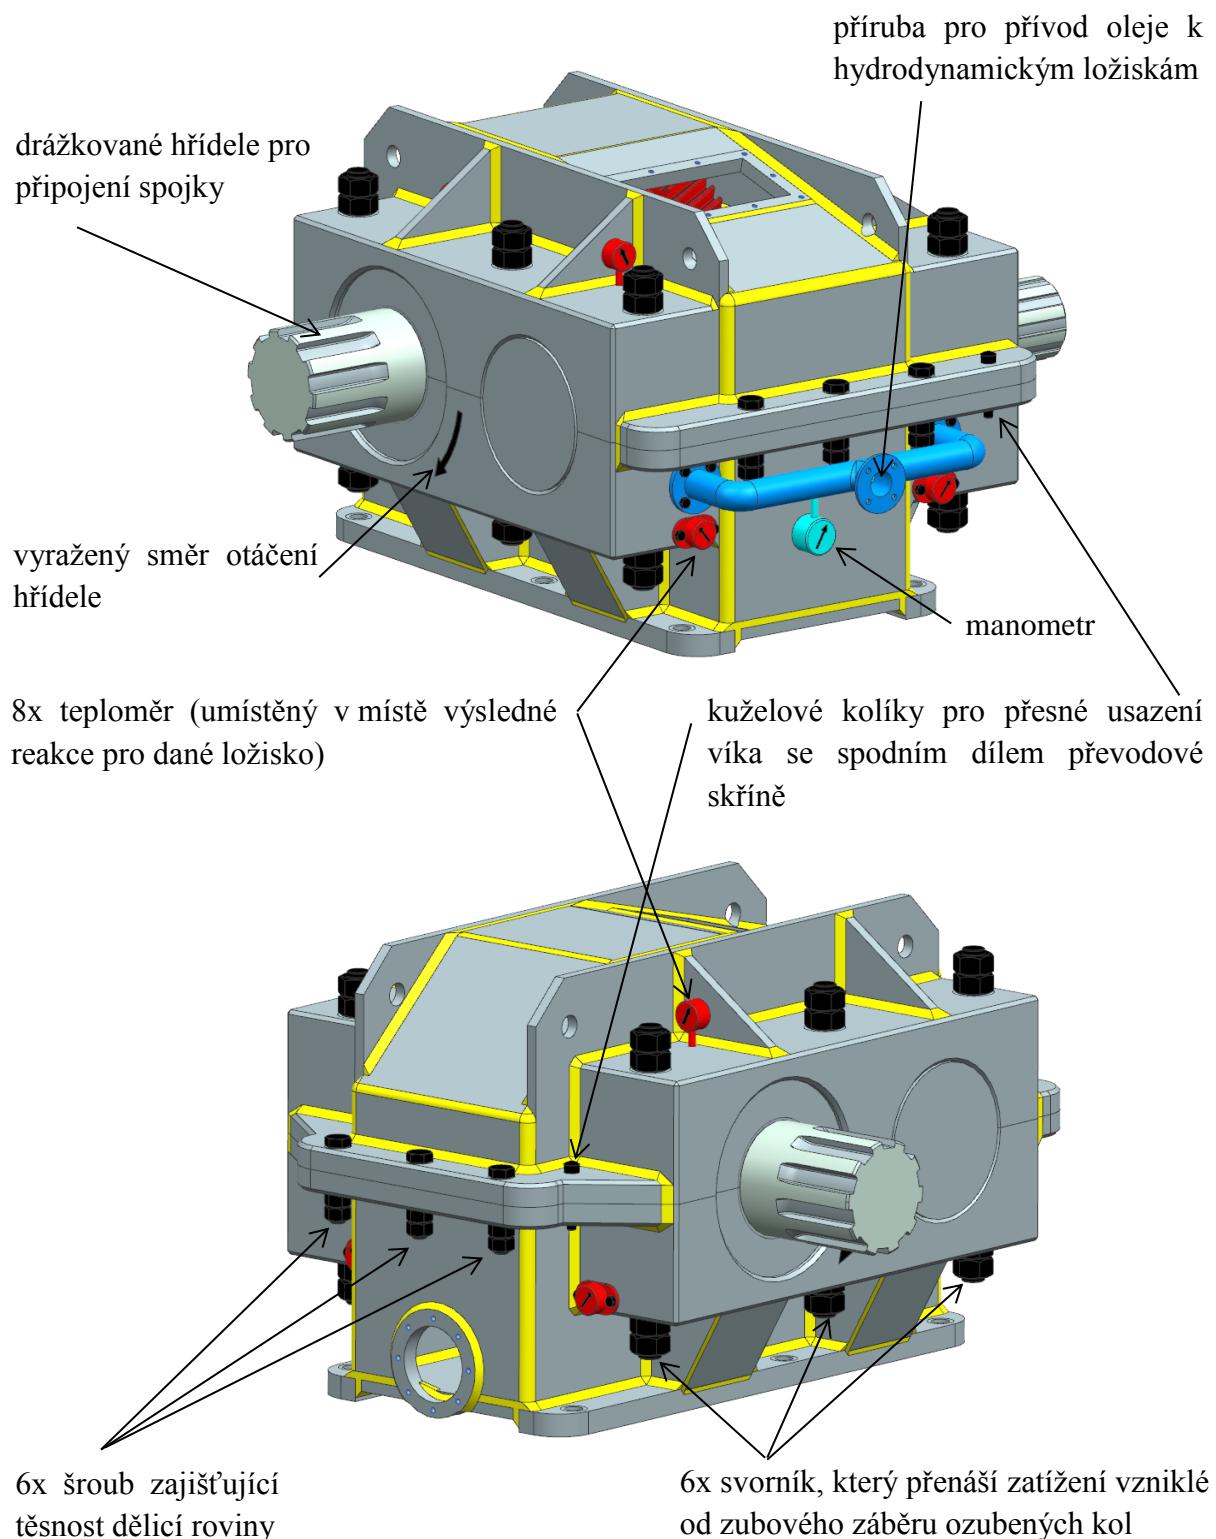

Poslední důležitou komponentou je utěsnění okolo hřídelů. Firma Wikov Gear s.r.o. si vyrábí vlastní dělená labyrintová těsnění, viz obr. 25. Tato speciální těsnění nejsou v přímém kontaktu s hřídelí, jako je tomu např. u gufera. Aby labyrintové těsnění plnilo svoji funkci, je opatřeno odstředivým kuželem, který je také součástí každé hřídele. Vlivem rotace hřídele dochází ke generování odstředivé síly, která působí na olej a má tendenci ho vracet zpět do převodové skříně.

## 8 MKP analýza převodové skříně

Metoda konečných prvků (MKP) je numerická metoda sloužící k simulaci průběhů napětí, deformací, vlastních frekvencí, proudění tepla, jevů elektromagnetismu, proudění tekutin atd. na vytvořeném fyzikálním modelu. Její princip spočívá v diskretizaci spojitého kontinua do určitého (konečného) počtu prvků, přičemž zjišťované parametry jsou určovány v jednotlivých uzlových bodech. MKP je užívána především pro kontrolu již navržených zařízení, nebo pro stanovení kritického (nejnamáhavějšího) místa konstrukce. Metoda konečných prvků je založena na Lagrangeově principu (těleso je v rovnováze, jestliže celková potenciální energie deformace soustavy je minimální).<sup>[2]</sup>

Výhodou této metody je snížení vývojového času a nákladů pro zavedení výroby. Vstupem pro tuto analýzu je navržený model převodové skříně v CAD (počítačem podporované projektování) programu, viz kapitola 7. Pro časové urychlení výpočtu je potřeba většinou model zjednodušit například o malé průměry děr, které neovlivňují námi zkoumanou a předpokládanou oblast maximálního napětí. Na tomto zjednodušeném modelu se dále aplikuje automatická síť konečných prvků, která je hlavní součástí MKP analýzy a jejíž kvalita ovlivňuje přesnost výsledných hodnot. Pro tento model jsem zvolil síť tvořenou čtyřstěny s mezi-uzly „CTETRA(10)“. Jeden takový prvek má celkem 10 uzlových bodů, které jsou základem pro tvorbu lineárních algebraických rovnic. Velikost tohoto elementu pro víko převodové skříně jsem zvolil o velikosti 20 [mm] a pro spodní část o velikosti 18 [mm]. Propojení sítě víka se spodní částí převodové skříně v jeden celek je provedeno pomocí funkce „Mesh Mating Condition“ ve kterém je nastavena vazba mezi jednotlivými uzly na hodnotu „free coincident“. Materiál převodové skříně je z konstrukční oceli typu 11 373, která má mez kluzu  $R_e = 220$  [MPa]. V této analýze jsem se zaměřil hlavně na odlehnutí dělicí roviny a na napětí, které bude působit na šrouby spojující tuto dělicí rovinu. Z tohoto důvodu je potřeba pro řešení zvolit síť i pro tyto šrouby. V programu NX jsem využil funkce, která nahrazuje skutečný šroub. Tato funkce nahrazuje šroub poddajným prvkem válcového průřezu o zvoleném průměru a hlavu šroubu s maticí takzvanou rigidovou růžicí, která je uvažována jako absolutně tuhý prvek typu „RBE3“. Pro přesnější výsledky bylo povoleno rigidové růžici propojení k mezi-uzlům u elementů převodové skříně. Pro svorníky přenášející hlavní zatížení je zvolen šroub M30. Ostatní šrouby zajišťující těsnost v dělicí rovině jsou M20. Poslední přípravou před zadáním okrajových podmínek byla aplikace 1D sítě typu „bod na plochu“ v dírách sloužících pro ustavení převodové skříně v požadované poloze. Tato 1D síť je zvolena jako absolutně tuhý prvek typu „RBE2“ a slouží k následnému zavedení potřebné okrajové podmínky nutné pro výpočet. Na obr. 27 je zobrazen celý model s vytvořenou sítí konečných prvků, na který se následně budou aplikovat okrajové podmínky.

## 8.1 Okrajové podmínky

Okrajové podmínky potřebné pro výpočet MKP analýzy je potřeba zvolit tak, abychom se přiblížili co nejvíce skutečným podmínkám při provozu převodové skříně. Špatnou volbou okrajových podmínek dochází ke zkresleným nebo nesmyslným výsledkům, které se snažíme eliminovat. Převodová skříň je ustavena v prostoru fixní vazbou odebírající 6 stupňů volnosti za jednotlivé body, nacházející se v dírách patek sloužících pro ustavení. Tyto body byly vytvořeny v minulé kapitole. Dále je zamezen posuv v ose z na spodních plochách patek, které zjednodušeně nahrazují pevný základ, na kterém je převodovka ustavena. Pro zjištění reálného chování v místě dělicí roviny byla využita kontaktní funkce „plocha na plochu“, která mnohonásobně prodlužuje celkový výpočetní čas. V této funkci je nutné zadat statický součinitel tření jednotlivých (ocelových) ploch. Tento součinitel byl zvolen pro daný materiál ze strojních tabulek s hodnotou 0,15 [–]. Posledními okrajovými podmínky je aplikace všech sil působících na převodovku. Pro větší stroje je uvažováno s gravitační silou, která může ovlivnit celkové výsledky. V dělicí rovině se nachází celkem 12 kusů šroubů, které přenášejí zatížení nebo slouží k jejímu utěsnění. Všechny tyto šrouby jsou předepjaty, aby nedocházelo k odlehnutí dělicí roviny a následným netěsnostem. Předepnutím se dále snižuje i cyklické namáhání šroubů. Sílu pro předepnutí svorníků jsem spočetl na orientační hodnotu 18,5 [kN]. Ostatní šrouby zajišťující těsnost v dělicí rovině byli předepjaty silou 15 [kN].

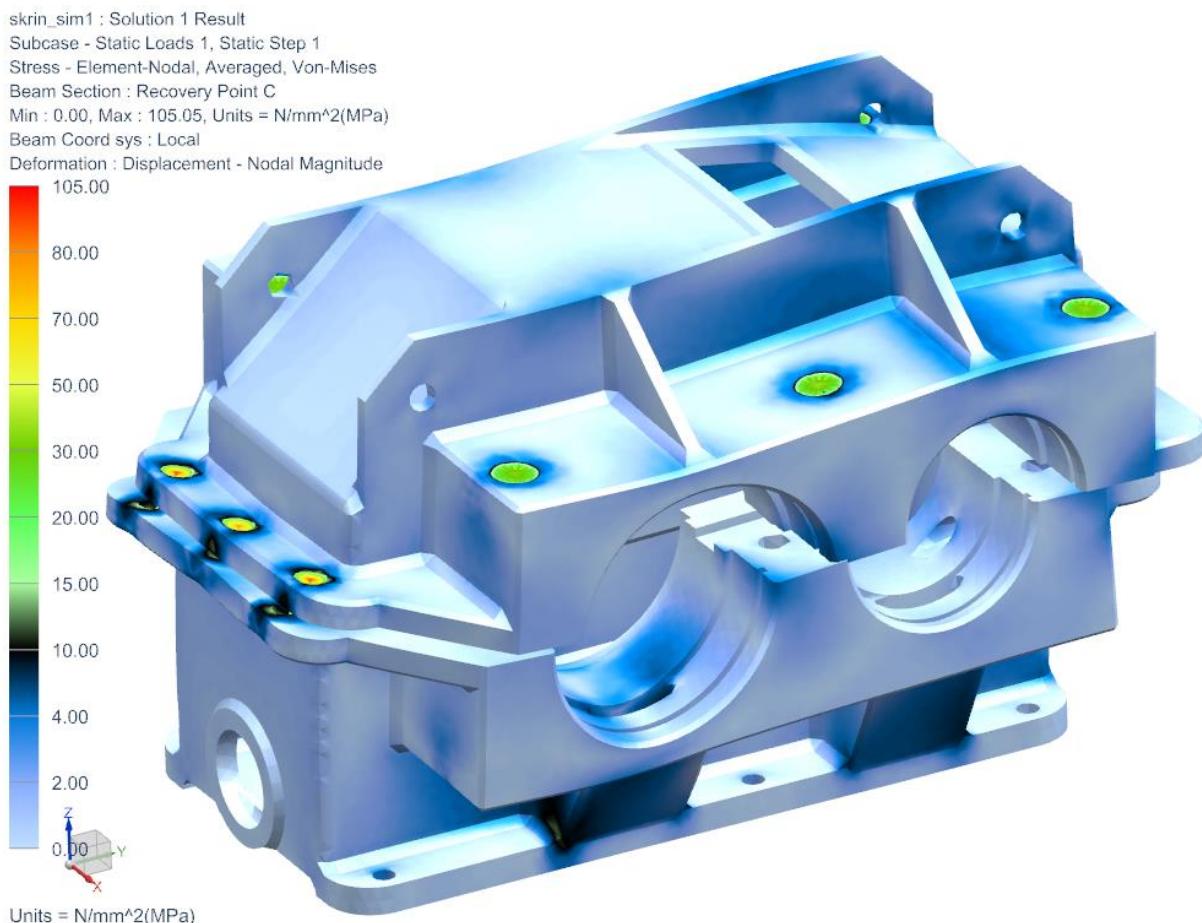

Hlavní zatěžující silou pro převodovku jsou výsledné reakce vznikající v místě hydrodynamických ložisek, viz tab. 11. Z těchto sil byla vybrána maximální síla, která nastane při využití převodu  $i_{21}$ . Jednotlivé směry a hodnoty sil působících v místě hydrodynamických ložisek byly aplikovány pomocí speciální funkce „bearing“, která je v nabídce programu NX. Výhodou použití této funkce je možnost volby parabolického rozložení každé síly, která se přibližuje skutečnému zátěžnému stavu. Jednotlivé okrajové podmínky jsou vidět na obr. 28.

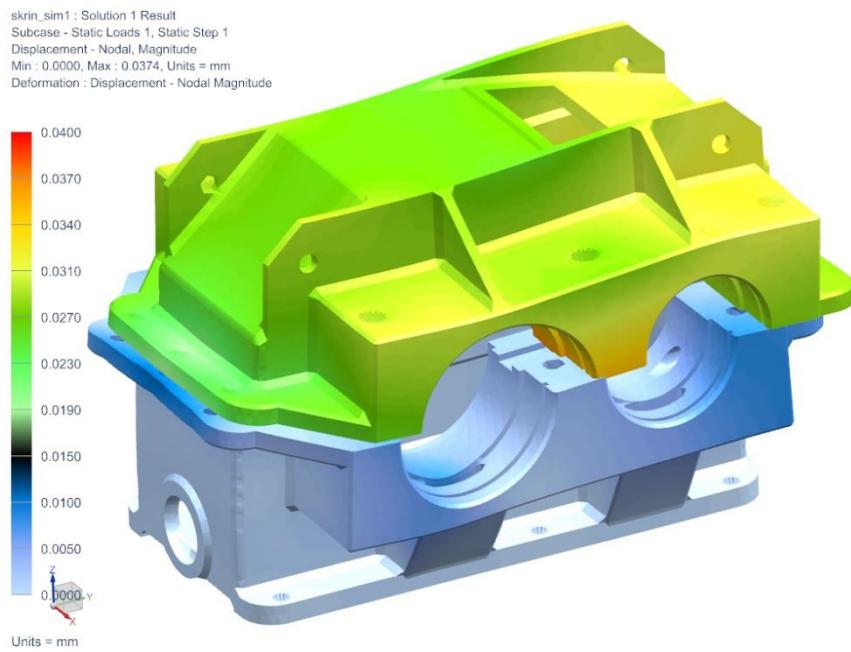

obr. 28 okrajové podmínky potřebné pro analýzu

## 8.2 Výsledky analýzy

Výsledky analýz jsou zobrazeny na obr. 29 - obr. 31. Pro čitelné zobrazení toho, jak se model převodové skříně chová při zatížení, je zobrazení modelu v 5 [%] měřítku deformace z modelu. Z obr. 30 je patrná deformace převodové skříně při maximálním možném zátěžném stavu. Jak je patrné z tohoto obrázku, nedochází pouze k odlehnutí víka od spodní části převodové skříně, ale dochází také k jejímu smýkání ve směru osy y. To je způsobeno tím, že výsledné reakce působí pod úhlem cca 22 [ $^{\circ}$ ] od osy z v rovině yz. Výsledné hodnoty posuvů jsou v rádech setin milimetru, které ve skutečnosti budou ještě nižší vlivem vložených hydrodynamických ložisek. Na obr. 29 je zobrazen průběh redukovaného napětí dle hypotézy HMH. Z výsledků je patrné, že maximální napětí v převodové skříni je cca 25 [MPa]. Při zvoleném materiálu převodové skříně z konstrukční oceli 11 373, která má mez kluzu  $R_e = 220$  [MPa], vychází koeficient bezpečnosti cca 8 [–]. Nejvíce namáhaným prvkem převodové skříně jsou jednotlivé šrouby. Redukované napětí ve šroubech se pohybuje v rozmezí od 30 do 95 [MPa] v závislosti na poloze jednotlivých šroubů. Maximální napětí s hodnotou 105 [MPa] je způsobeno vlivem lokální nepřesnosti sítě.

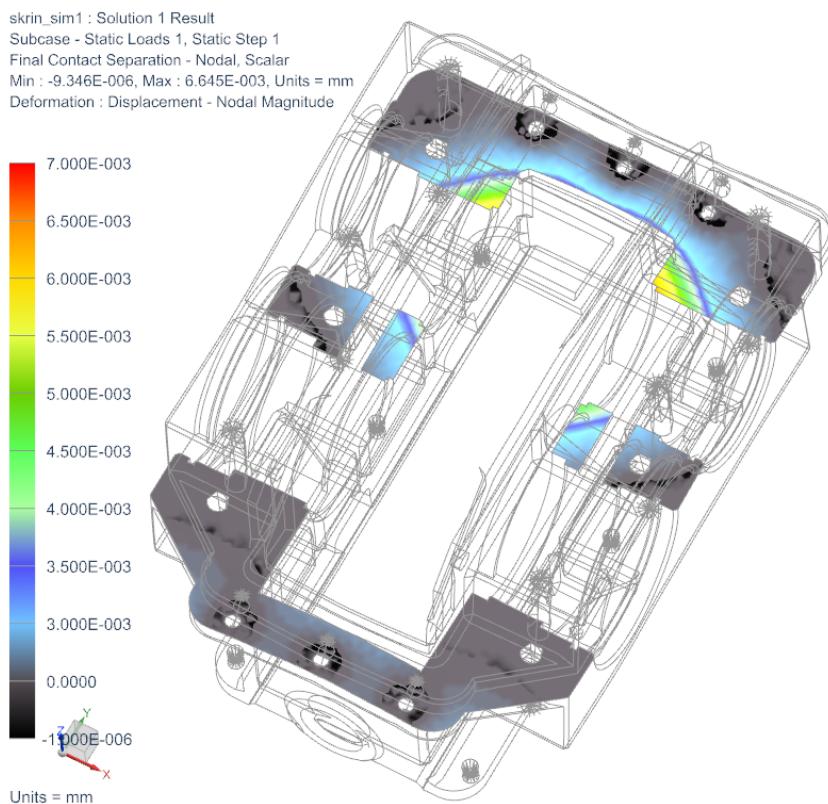

obr. 29 průběh redukovaného napětí v převodové skříni dle hypotézy HMH

obr. 30 deformace převodové skříně

### 8.2.1 Odlehnutí ploch v dělicí rovině

Na obr. 31 je zobrazeno odlehnutí víka od spodní části převodové skříně. Z obrázku je patrné, že k největšímu odlehnutí dochází právě v místech, kde působí výsledné reakce v uložení hřídelů do vrchní části, tj. víka převodové skříně. Z výsledků lze snadno rozpoznat, že při působení této maximální zátěžné síly bude převodová skříň při dodržení předepnutí jednotlivých šroubů 100 [%] utěsněna.

## 9 Technicko-ekonomické zhodnocení

Technicko-ekonomické zhodnocení procesu slouží ke stanovení nákladů, které jsou potřebné k uskutečnění výroby zadané součásti. Technické zhodnocení je potřebné k určení parametrů výroby a tím zjištění, zda je součást vyrobitevná. Ekonomické zhodnocení je zapotřebí především ke stanovení prodejní ceny a tržeb firmy. K tomuto zhodnocení poslouží tab. 15, kde se stanoví jednotlivé reálné varianty výroby, a posouzením vlivu jednotlivých faktorů získáme nejlepší variantu.

Každý sloupec tabulky nám dává na výběr způsoby výroby převodovky při zachování dané funkce. Variant výroby může být několik, ale dle zadání diplomové práce je většina těchto parametrů předem stanovena.

Varianta A zobrazuje požadavky na výrobu převodovky dané firmou Wikov Gear s.r.o. Variantu B bych zvolil při požadavku na levnější výrobu, kdy bych hydrodynamická ložiska změnil za valivá, která jsou ekonomičtější, ale snižují účinnost pomocné převodovky. Změna ložiska má také za následek zjednodušení převodové skříně a snížení požadavku na mazání ložisek.

	Varianta A	Varianta B

Firma Wikov Gear s.r.o. pro tuto práci poskytnula skutečné ceny jednotlivých hlavních dílů vyráběné převodovky, viz tab. 16, která se podobá svou velikostí a přenášeným výkonem pomocné převodovce zpracované v této práci. Výrobní ceny uvažují stejné s jediným rozdílem, kterým je počet kusů pomaloběžné a rychloběžné hřídele s ozubením pro možnost změny převodového poměru. Pro tuto pomocnou převodovku bylo zapotřebí použít 4 pomaloběžné a rychloběžné hřídele. Výrobní cenu celé pomocné převodovky varianty A odhaduji přibližně na 1 862 700 [Kč].

Aby bylo možné porovnat náklady potřebné na výrobu pomocné převodovky varianty B, požádal jsem firmu SKF o zaslání cenové nabídky na různé druhy ložisek viz tab. 17. Tyto druhy ložisek jsem stanovil po předběžných výpočtech a všechna vydrží maximální namáhání stanovené v tab. 11. Výrobní cenu této pomocné převodovky varianty B odhaduji přibližně na 1 700 000 [Kč].

## 10 Dynamické zatížení převodové skříně

Převodová skříň je vystavena dynamickým účinkům sil vznikajícím z rotace hřídelí a ozubených kol. Při tomto dynamickém namáhání může docházet k rezonančnímu stavu převodové skříně nebo hřídelí. Tento stav je nepřijemnou skutečností každého točivého stroje. Způsobuje vysoké hodnoty deformací jednotlivých prvků a je potřeba se těmto rezonančním stavům vyhnout. Tyto rezonanční stavy nastávají tehdy, jeli budicí frekvence rovna vlastní frekvenci dané součásti. Budicí frekvence je přímo úměrná otáčkám jednotlivých hřídelí a ozubených kol. Jelikož tato pomocná převodovka může pracovat ve velkém rozsahu otáček, nemělo by docházet ke stavu rezonance v celém rozsahu otáček. Vlastní frekvence a příslušné tvary kmitů lze zjistit například výpočetní technikou. Jelikož převodovka a tudíž i hydrodynamická ložiska pracují ve velkém rozsahu otáček a různých zatěžujících spektrech, nelze přesně určit jednotlivé tuhosti a útlumy pro jednotlivá hydrodynamická ložiska. Tyto měnící se tuhosti a útlumy jsou vstupním a také hlavním parametrem pro zjištění skutečných vlastních frekvencí. Stanovení správných vlastních frekvencí se vymyká rozsahu této diplomové práce a jejich určení by v tomto případě bylo velice obtížné.

Jednotlivé rezonanční stavy lze také zjistit na již vyrobené převodovce za jejího provozu. Toho lze dosáhnout měřením na předpokládaných kritických místech nebo místech, kde je potřeba diagnostiky kvůli možné predikci poruchy. Pokud by na této pomocné převodovce docházelo k rezonančnímu stavu, bylo by jediným řešením převodovou skříň dodatečně využít pomocným vhodně umístěným žebrem nebo se vyhnout kritickým otáčkám, způsobujícím rezonanční stav. Vzhledem ke zvoleným rozměrům jednotlivých hřídelů a zvolené tloušťky plechů pro výrobu převodové skříně můžeme předpokládat, že k rezonančním stavům nebude docházet.

## 11 Závěr

V této diplomové práci jsem se zabýval návrhem pomocné převodovky pro zkušebnu, kterou by chtěli využívat ve firmě Wikov Gear s.r.o. pro testování průmyslových převodovek. Vzhledem k jednoznačnému zadání jsem neměl příliš velkou možnost výběru různých konstrukčních variant. V práci jsem se tedy zaměřil hlavně na praktické výpočty a snažil se je shrnout do praktických grafů a tabulek, které popisují provozní stavy pomocné převodovky. Na základě těchto údajů jsem navrhl a vymodeloval univerzální převodovou skříň s ostatními převody a příslušenstvím. Pomocí simulačního softwaru jsem celý model otestoval na nejvyšší zátěžný stav. Zajímavým výsledkem je zobrazení odlehnutí dělicí roviny, které může vést při špatném návrhu k netěsnostem převodové skříně a úniku oleje, který je vždy nežádoucí. Tuto práci hodnotím jako velice zajímavou, protože požadované převody nejsou z finanční náročnosti ředitelné, ale musí se vždy pro testování na daný stav mechanicky vyměnit. V této práci jsem se hlouběji ponořil do problematiky návrhu převodovek a naučil se zpracování ve výpočtovém softwaru KISSOFT. Díky tomu se prohloubily moje zkušenosti a vědomosti v této oblasti konstrukcí.

**Important hint: At least one warning has occurred during the calculation:**

1-> The circumferential speed is very high ( 27.1517 m/s)!

You have to take adequate action to guarantee proper lubrication.

2-> Notice to gear 1:

NOT POSSIBLE TO MEASURE BASE TANGENT LENGTH!

The width of the gear is too small, hence the tooth thickness too big, so that the required length for the measurement exceed the face width.

**REMARKS:**

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances  
Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances  
The calculation is done for the Operating pitch circle..

**Important hint: At least one warning has occurred during the calculation:**

1-> Notice to gear 1:

NOT POSSIBLE TO MEASURE BASE TANGENT LENGTH!

The width of the gear is too small, hence the tooth thickness too big,  
so that the required length for the measurement exceed the face width.

**CALCULATION OF A HELICAL GEAR PAIR**

**9. DETERMINATION OF TOOTHFORM**

Data for the tooth form calculation :  
Data not available.

**REMARKS:**

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances  
Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances  
The calculation is done for the Operating pitch circle..
- Details of calculation method:  
cg according to method B  
KV according to method B  
KH<sub>b</sub>, KF<sub>b</sub> according method C  
KH<sub>a</sub>, KF<sub>a</sub> according to method B

**Important hint: At least one warning has occurred during the calculation:**

1-> The circumferential speed is very high ( 24.9200 m/s)!

You have to take adequate action to guarantee proper lubrication.

2-> Notice to gear 1:

NOT POSSIBLE TO MEASURE BASE TANGENT LENGTH!

The width of the gear is too small, hence the tooth thickness too big, so that the required length for the measurement exceed the face width.

#### **9. DETERMINATION OF TOOTHFORM**

Data for the tooth form calculation :  
Data not available.

**REMARKS:**

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances  
Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances  
The calculation is done for the Operating pitch circle..
- Details of calculation method:  
cg according to method B  
KV according to method B  
KH<sub>b</sub>, KF<sub>b</sub> according method C

**Important hint: At least one warning has occurred during the calculation:**

1-> Notice to gear 1:

NOT POSSIBLE TO MEASURE BASE TANGENT LENGTH!

The width of the gear is too small, hence the tooth thickness too big,  
so that the required length for the measurement exceed the face width.

**9. DETERMINATION OF TOOTHFORM**

Data for the tooth form calculation :  
Data not available.

**REMARKS:**

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances  
Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances  
The calculation is done for the Operating pitch circle..
- Details of calculation method:  
cg according to method B  
KV according to method B  
KH<sub>b</sub>, KF<sub>b</sub> according method C

**Important hint: At least one warning has occurred during the calculation:**

1-> The circumferential speed is very high ( 22.3165 m/s )!  
You have to take adequate action to guarantee proper lubrication.

2-> Notice:  
Gear 1 :  
Measuring the Base tangent length is critical,  
it is better to use measurement over rolls!

#### **9. DETERMINATION OF TOOTHFORM**

Data for the tooth form calculation :  
Data not available.

##### REMARKS:

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances  
Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances
- The calculation is done for the Operating pitch circle..
- Details of calculation method:  
cg according to method B  
KV according to method B  
KHb, KFb according method C

**9. DETERMINATION OF TOOTHFORM**

Data for the tooth form calculation :  
Data not available.

**REMARKS:**

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances
- Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances
- The calculation is done for the Operating pitch circle..
- Details of calculation method:  
cg according to method B  
KV according to method B  
KH<sub>b</sub>, KF<sub>b</sub> according method C  
KH<sub>a</sub>, KF<sub>a</sub> according to method B

**Important hint: At least one warning has occurred during the calculation:**

1-> The circumferential speed is very high ( 20.0848 m/s)!  
You have to take adequate action to  
guarantee proper lubrication.

## 9. DETERMINATION OF TOOTHFORM

Data for the tooth form calculation :  
Data not available.

REMARKS:

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with consideration of all tolerances  
Specifications with [.m] imply: Mean value within tolerance
- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances  
The calculation is done for the Operating pitch circle..
- Details of calculation method:  
cg according to method B  
KV according to method B  
KH<sub>b</sub>, KF<sub>b</sub> according method C  
KH<sub>a</sub>, KF<sub>a</sub> according to method B

## 9. DETERMINATION OF TOOTHFORM

Data for the tooth form calculation :  
Data not available.

### REMARKS:

- Specifications with [.e/i] imply: Maximum [e] and Minimal value [i] with

consideration of all tolerances

Specifications with [.m] imply: Mean value within tolerance

- For the backlash tolerance, the center distance tolerances and the tooth thickness deviation are taken into account. Shown is the maximal and the minimal backlash corresponding the largest resp. the smallest allowances

The calculation is done for the Operating pitch circle..

- Details of calculation method:

cg according to method B

KV according to method B

KHb, KFb according method C

KHa, KFa according to method B

# SIZE CODES

Waukesha Tilting Pad Radial Bearings are identified by a two part code which consists of the bearing size followed by a suffix indicating the type of construction.

The size designation is shown in the left-hand column of the Size Tables on Pg. 19 while the suffix options are shown below.

In addition to the basic two part code, various additional features can be specified by referencing an appropriate Style option from Pg. 11. Note than in many cases the use of the Style designation does not completely describe the feature required and additional information is required.

## Code Nomenclature

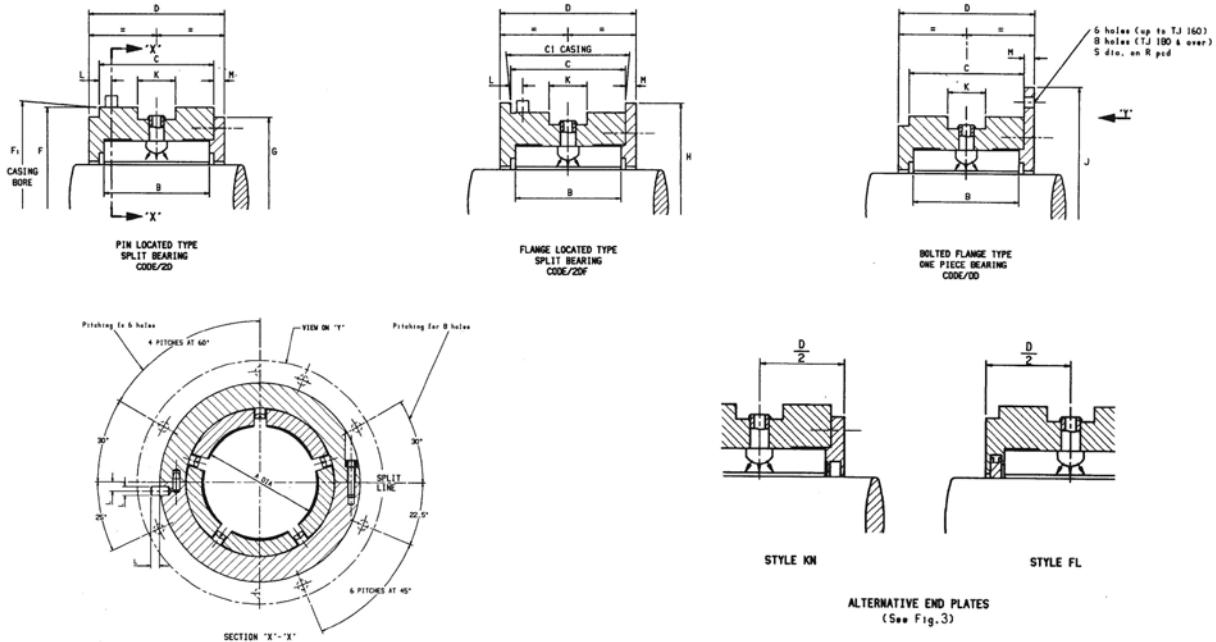

### Style Options (see Section 6):

AP	= Adjustable pivots	IT1	= Provision for customer supply temperature sensors	OP	= Offset pivot pads
AR60	= 60° arc pads on Series TF Bearings	IT2	= Temperatures sensors (Waukesha supply)	TLG or TLG2	= Single or double plain grooved axial face
BP	= Two pad orientation	IR	= Provision for customer supply proximity probes	TLU or TLU2	= Single or double taper land axial face (uni-directional)
CL	= Curved line pivot	J	= Hydrostatic jacking	TLB or TLB2	= Single or double taper land axial face (bi-directional)
FL or FL2	= Single or double floating seal	KN or KN2	= Single or double knife edge end plate	TP or TP2	= Single or double tilting pad axial face

Examples of complete bearing reference codes which should be used for orders or enquiries are as follows:

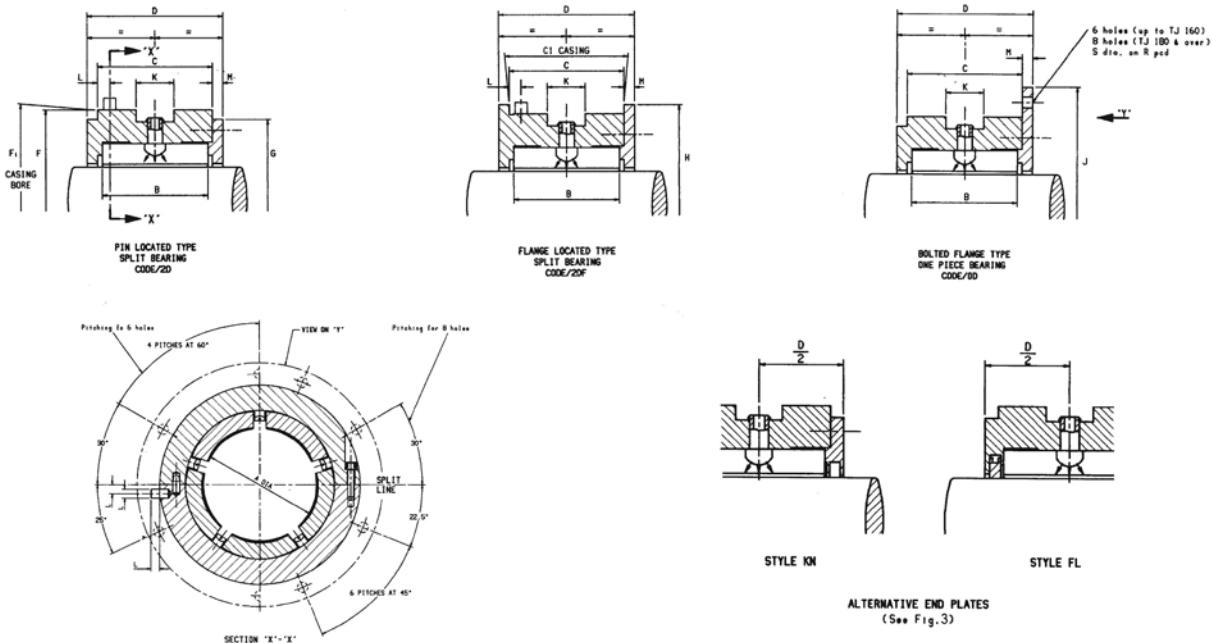

Code	Description
TJ050-020/2D	50mm 5 pad bearing, b/d = 0.4, split, pin located
TJ100-100/OD	100mm 5 pad bearing, b/d = 1.0, one piece, flange located
TF120-084/2DF Style J	120mm 4 pad bearing, b/d = 0.7, split, flange located with jacking
TJ200-080/2DF Style BP, FL, IR	200mm 5 pad bearing, b/d = 0.4, split, flange located with two pad orientation, single floating seal and provision for radial proximity probes
TJ250-250/2DF Style TP2	250mm 5 pad bearing, b/d = 1.0, split, flange located with tilting pad axial faces on both ends

## Orders & Enquiries

When enquiring for or ordering Waukesha Tilting Pad Radial Bearings from this Handbook, we recommend that the anticipated operating conditions are given so that confirmation can be given for the bearing selection. Please use the Data Sheet on Pg. 25 or state the following:

1. Application.
2. Shaft diameter – with tolerance if non-standard shaft to be used.
3. Shaft speed – normal and maximum.
4. Load – normal, maximum and at start-up, also angle and whether steady or rotating.
5. Oil grade to be used – also inlet temperature and pressure at entry to the bearing.
6. Optional features – If these are required, additional information may be needed as indicated in the appropriate Style description.

## Sense of rotation

The shaft axis runs along the positive y-direction (left to right in the graphical Shaft editor). In the Shaft editor, the Z-axis points upwards, the X-axis points towards the user. A right-hand rotation of the shaft around the positive y-axis direction is specified as "clockwise". The next figure shows the direction of these co-ordinates and the positive direction of forces and moments. Please note that weight has an effect in the negative Z-direction if the shaft is positioned horizontally.

Definition of Co-ordinate System

Positive Direction of Forces and Moments

In most force elements, the directions of the moments is usually defined by the terms "driving" and "driven". The entry "driving" means either that the shaft drives (an external application) or that the torque runs counter to the sense of rotation (i.e. the shaft loses power). The entry "driven" means either that the shaft is driven from outside (e.g. by a motor) or that the torque runs in the same direction as the sense of rotation (i.e. the shaft is supplied with power).

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

#### Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

#### Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

#### Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

#### Remarks:

- The shearing force is not considered in the analysis according to DIN 743..
- Cross section with square groove:  
The reference diameter for the notch number is not defined.  
Therefore the shaft diameter is taken as reference diameter..
- Cross section with interference fit:  
The notching factor for the light fit case is no longer defined in DIN 743.  
The values are imported from the FKM-Guideline..

		Jm. Výkon měniče při dodání 550 kW
		Jm. Proud měniče při dodání 990 A
		Jm. výkon/110% moment. přetížitelnost 710 kW
		Jm. proud/110% proud. přetížitelnost 1260 A
		Typová řada VLT® AutomationDrive
		Varianta FC-302 AutomationDrive Rozšíř.
		Jmenovitý výkon 630 KW
		Počet fází Trojfázový
		Jmenovité napájení 380 - 500 VAC
		Enclosure IP21 / Type 1
		RFI filtr RFI filtr třídy A2
		Brzdný střídač, Safe Stop Bez brzdného střídače
		Ovládací panel Grafický ovládací panel
		Přídavné lakování S přídavným lakov. ploš. spojů
